GLEANINGS IN A JOURNAL DEVOTED TO BEES AND HONEY AND HOME INTERESTS. **BEE CULTURE** ILLUSTRATED SEMI-MONTHLY Published by THE A. ROOT CO. \$1.00 PER YEAR MEDINA, OHIO.

Vol. XXIII.

JAN. 1, 1895.

No. 1.

STRAY STRAWS FROM DR. C. C. MILLER.

HAPPY new-year!

THE WAR IS ON in *Progressive* between the five-banders and the anti-five-banders.

OHIO OFFICERS, I see by the papers, are looking up syrups bleached by zinc poison.

THE HAINAUT Bee-keepers' Association, Belgium, numbers more than 2000 members.

FOUNDATION-MACHINES are getting it down pretty fine to make a septum $\frac{1}{10000}$ of an inch thick. That's 185 thicknesses to the inch.

WOOD SEPARATORS, if loose; tin, if nailed, has been my rule; but perhaps it will be all right to nail wood if only one nail is put in each end.

M. M. BALDRIDGE, St. Charles, Ill., is getting out some interesting bulletins concerning sweet clover, compiled from government reports and other reliable sources.

THE BAKING or scrubbing motion of bees in front of the hive is only for amusement, according to S. E. Miller in *Progressive*. Why not? Or for exercise?

"SYRUPS that have been adulterated with glucose, and preserves that have been sweetened therewith, become a menace to health."—Dr. Eccles, in *N. Y. Med. Journal*.

LATHYRIS SILVESTRIS, growing a few miles from me, was seriously if not fatally injured by the terrible drouth of last summer. Sorry. Sweet clover's the chap for drouth.

SAY, BROTHER A. I., after that performance in flesh-colored tights, described on p. 954, don't you grumble any more about the way they dressed in the St. Joe variety show. "Oh-ow!"

HASTY, in his condensed cream in *Review*, objects to using old bedclothes in percolating feeders. Wants them, "like Caesar's wife, above suspicion and snuffin'." I am with you, Hasty.

REPORTS from Germany say large numbers of dead bees are found as a result of working on

Chelidonium majus. Possibly some of the strange cases of mortality in this country have been caused by working on poisonous plants.

FROM THE WAY C. A. Hatch speaks of that Russian smoker on p. 943, he would hardly approve of my first smoker. It was a preserving-kettle with a tin cover and a rubber tube. It wasn't as good as the Crane!

THE CONTROVERSY, "Ten vs. eight frames," seems changing into "ten frames in one story, vs. sixteen frames in two stories." How about compromising on fourteen frames in two stories? [Better make it $14\frac{1}{2}$, eh?—ED.]

AN ARTICLE in a leading Chicago daily gravely states that dark beeswax comes from Wisconsin, where the bees work on tobacco. [Let's get that Chicago daily to settle for us that vexed question of large vs. small hives.—ED.]

DR. PAUL MARCHAL reports in *Apiculteur* that he dissected 98 workers taken from a hive of laying workers, and found among them 20 containing eggs fully developed, and a goodly number with eggs in various stages of partial development.

SUPPOSE one convention had all essays and another all discussions. Other things being equal, which convention would you attend? [I'd attend the last; but I'd go further to one having the right proportion of both. The essays of the right sort should stimulate discussion.—ED.]

WAX ADULTERATION is hardly as bad here as elsewhere. At any rate, I see mention in *Le Rucher* of a brochure of 16 pages on the principal adulterations of beeswax. [The fact is, bee-keepers of this country wouldn't have adulterated wax, even if cheaper, and none of the present American makers would furnish it.—ED.]

S. M. KEELER, in *American Bee-keeper*, recommends red lead and linseed oil to make inside corners of a feeder water-tight; and the clasps worn by wheelmen, to make your trouser-legs bee-tight. [I have used the clasps myself. I always use them on long pants for wheel-riding; so you see that, when I take a spin to an out-yard, my trousers are bee-tight at the minute of my arrival, and during my stay there.—ED.]

THE ABUSE of a good thing is no argument against its proper use. Like John Handel, p. 944, I've coaxed bees up into the eighth story and had all unfinished sections; but, all the same, when I'm pretty sure bees will fill a second super, I put the second one under. If doubtful about both being filled I put the empty one over.

"FOR MANY YEARS I have warned bee-keepers to watch the sudden checks in honey-flows when colonies had large quantities of larvæ on hand, and to feed, no matter how much old sealed honey the bees might have at the time, because brood is never as well fed as when there is plenty of *unsealed* honey in the brood-chambers."—Wm. EcEvoy, in *C. B. J.*

NOW WE KNOW the object of those long essays. It was to get the papers of St. Joe to print them, as they would print them and wouldn't print discussions. Bro. Abbott, St. Joe papers can get points from our Marengo papers. A horticultural convention was held here lately, and a report of four columns gave the discussions while not an essay was printed, although some good ones were read. But then, our editors have lots of judgment and enterprise.

"HUSBAND AND WIFE should kiss each other, but not on the street-corners, as a general thing," quoth Hasty in *Review*. What business has an old bachelor putting restrictions on the kissing of man and wife? Besides, if he were experienced in that sort of thing he'd know it was a good deal nicer to kiss them on the lips. [You'll have Dr. Peiro after you if you don't look out. He objects to the "lip" part of the job, and he's no bachelor either.—Ed.]

IT TURNS OUT that Doolittle, the champion of brace and burr combs, has been for years using such top-bars and spaces as keep him almost free of the nuisances. He says, in *A. B. J.*, "With such frames and bee-spaces it is a rare thing that any honey is ever stored between the sections and tops of frames, while not to exceed from 5 to 15 brace or burr combs are found jutting above the tops of the frames." If we all get down to 5 or 15 bits of dry wax we'll do not so badly. [So Doolittle is an anti-brace-comb man after all, in practice.—Ed.]

THIRTY THOUSAND, OR, to be more exact, 30,067, is the number of members of the German Central Association for Bee Culture and its branches. I think no bee-keepers' society in this country is so large. [These figures look tremendous when we in our country can not get up a membership of over 100, and that, too, for an association that is somewhat international in character, in the best bee country in the world. Of course, we have great geographical distances to contend with; but this can not account for such a difference. I should like to know how the Germans manage to secure so

large a membership; the conditions of membership, and the privileges.—Ed.]

BEE-ESCAPE.

THE PHILOSOPHY OF THE WORKING OF THE STAMPEDE ESCAPE.

By C. W. Dayton.

Editor Gleanings:—It is admitted (I refer to page 870) that the Stampede escape resembles the original "flood-gate" Poulder, and the "going-toward-the light" Boardman, as closely as if devised by a theorist who had never possessed a colony of bees. Still, by the method of procedure the Stampede might possibly have been produced had neither of these escapes been in existence.

I used escapes very much as toys or curiosities until the season of 1892, when I engaged with Mr. Charles Adams, of Colorado, where about five dozen Porter escapes were to be utilized in our regular work. The following winter there came a discussion of escapes in the *Review*, and it was claimed that an exit which admitted only one bee at a time was as good as a larger exit. It was suggested by the writer that something was lacking in the present forms of escapes, because, when they were in use there was a clicking and crackling sound to be heard; and after removing the cleared super the escape-board was nearly always found strewn with slivers, and the joints were rounded by the gnawings of the confined bees. Mr. Aikin's experience agreed with this, and he said that what was needed was a large window to show the bees the way. I waited confidently for some one to provide the escape which should eliminate these supposed troubles.

In using escapes during 1893 the crackling was still present, the joints of hives and supers were being rounded, and as the supers were raised the bees sprang into the open space as if to get fresh air, but very few took wing. These actions indicated that a way of departure was desired, though they were not in haste to depart by it. Again, where hives had too small entrances, this crackling sound had been noticed to proceed from the neighborhood of crevices between supers and covers. When the entrances were enlarged, the crackling all ceased. Entrances which were large enough for colonies while weak, were too small after the colony became stronger. Bees had been observed trying to enlarge, not alone the usual entrance, but also every visible crevice about their hive. Although the enlargement of all the crevices is not in accordance with reason, we find that the nature of bees impels them to the removal of a

mountain with as much vigor as in sweeping away the loose dirt which a mole may have thrown upon their doorsill.

Several escapes and supers were prepared so that it could be seen how the bees performed. It was noticed that the first one or two hundred bees proceeded almost directly to the joints, and began pulling at the corners without much search for the escape-exit. These bees seem to bear about the same relation to the general throng as the sentinels in a colony or the leaders in a swarm. A single-exit Porter escape had the rear part of the channel removed, and then it was adjusted on the top of the escape-board with its mouth projecting through the side of the super, to allow light to shine through the escape and be distributed over the surface of the board. Loud crackling ceased entirely. Still, very few bees came out through the escape during the first hour. A Porter escape was thus arranged for the outside air and light, and then another by the side of it, in the usual way, leading down into the brood-nest, and four-fifths of the bees went out of the super by the inside rather than by the outside route. Why should they *not* choose the shortest way?

Another modification of the Porter escape was devised, containing a long flexible spring for a bee to walk upon, and which should sag and open the exit, allowing the bee to escape without effort. In testing it by the side of the usual exit, 95 to 98 out of 100 bees passed out of the exit, which required no exertion. One hundred bees were placed in a box with the exits side by side. When the bees were quietly caged they remained unalarmed for considerable time. When the exits were closed until they became uneasy, the difference in operation of the exits was much nearer alike, owing to one bee first spreading the springs and then several others rushing and following closely after. It requires a fresh quota of bees at each trial, because the natural disposition of the bees is the subject of test.

An easy exit would assist slight inclinations, and a single-bee exit is inadequate for practical use, as an hour or so after the escape-board is put on the hive, the festoons begin to break up; and I have seen bees crowd through a single-exit Porter escape, pressing the springs apart the full width of the channel. The wider the springs are opened, the more power is required. This fact suggested the change to laterally swinging gates, which might be maintained open full width as easily as part way, after the manner of the "garden gate," which swings by its own weight upon a narrow hinge at the top and a hinge of wider sweep for the bottom. Then it was noticed that robbers, in trying to creep into perpendicular crevices, approached from the sides, showing that the natural mode was to place their heads under and lift, instead of pushing against the points of the shoulders, as would be necessary in the operation of later-

al gates and springs. Therefore the Poulder was the correct form of gate. The force of the Poulder invention was destroyed by the advice to "let the points of the pins rest upon the jumping-off board," when they should have remained up far enough to nearly admit a bee. This gate, constructed of heavy tin and, properly adjusted, clears the supers right along; but with the front edge of the heavy gate resting upon the "jumping-off" board, it is of no use whatever. I made it first of tin, using it so one season; then platinum, and finally of wire, to admit a better flow of light. I believe the "partially open" idea was first suggested and applied to escapes by the Porters.

In my opinion, the first bees to leave the combs and come down on the escape-board are not dispositioned to leave the apartment until the whole "crowd" goes. They search or a route of escape, and, finding none which *suits* them, they attempt to prepare one by pulling away at the yielding points. If a satisfactory exit is there, they recognize the escape-board as a strange piece of furniture, and spend the waiting-hour examining each other for detection of a possible stranger. About the time the bees were expected to be moving through the gate of the Stamped escape, the space between the gate and screened window was discovered to be packed full of bees, there being several upon the upper and brood-nest side of the gate, clawing and pulling for dear life to gain admittance from the hive into the super. Certainly it would take a muscular bee to lift this gate while several bees were trying, with weight and strength, to hold it down, and the roof of the channel at their backs. At first they were thought to be bees from the brood-chamber coming up, and it looked like an insurmountable obstacle. Then it was wondered why they were so anxious, having no knowledge of what would be found on getting through the gate. Finally it was discovered that these were bees of the super, which had inadvertently gone under the gates and then decided that they must return or be forever separated from their sisters. When the general tumult or stampede began, the tide turned the other direction.

As evidence of the stampeding disposition of bees, I will relate: A strong colony was prepared for queen-rearing by removing the upper story and setting the same on the old stand, while the lower story containing the brood and queen was carried to a distant stand. In the morning it was intended to add more bees and give eggs for cell-building to the queenless half. This division was made near dusk, and about two hours later I heard a loud roaring in the apiary. On going out I found the bees of this queenless half pouring out and marching off across the grass and entering a strange hive about three feet away. Both hives were black with fanning bees, and the trail of march was at least fifteen inches wide. This was he

greatest demonstration over the loss of a queen that I ever saw. Yet was it not the exact result produced by the adjusting of an escape-board between the two stories? And what of the efficacy of the one-bee-at-a-time exit?

Mrs. Atchley wrote some time ago, that, while some colonies would mourn greatly over the loss of the queen, there were others which mourn scarcely any. There is as much difference in colonies in leaving the supers or going through escapes, and it is advantageous to assist those which are slow to mourn and move, by the application of carbolized cloths. That form of escape which clears the supers in the shortest length of time is not correspondingly the most desirable for use. For example, a large amount of smoke will soon drive bees from one super into another, but a lesser amount of smoke, and slower traveling, may leave them in better condition to resume work in the new super. An escape does not smoke; but a one-bee exit may waste their thronging tendency, or the air of the super may become so heated as to injure the health of the bees. Such fear of suffocation clears a super more thoroughly, because, in going out by the natural impulse, there is a number of bees which linger, as guards of the combs of honey. The getting of the *main force* of bees below *contentedly at work* in the new super is the practical consideration.

Florence, Cal., Dec. 1.

[I have read over the foregoing with more than ordinary interest. While Mr. Dayton has written other good articles on this subject, this one, it seems to me, is the most comprehensive from his pen so far, and comes the nearest to hitting the real secret upon which bee escapes do their work.

Yes, I will admit that the Stampede (in fact, I assumed as much in my answer on page 870) might have been produced without the knowledge of either of the other two inventions.

Although Mr. Dayton seems to have covered the ground very fully, I wish we might have corroborative testimony from others.—Ed.]

COVERS FOR HIVES.

THE HIGGINSVILLE AND GABLE DISCUSSED

By Dr. C. C. Miller.

Early in November we had a fall of snow, and, unfortunately, my hives were not yet in the cellar, so each one had a covering of snow some three inches thick. In a day or so there was a sort of basin of snow on each hive. On the middle part of the hive-cover the snow was entirely gone, while at the outer edge there remained a border of snow three inches deep. There was some comfort in the thought that the colonies were strong enough so that the heat from them melted the snow. Of course, the heat would be greatest at the middle part, directly over the cluster, while at the outer part there was not enough heat to melt the snow.

But there was discomfort in the thought that whatever heat came up to melt the snow was heat taken from the bees, and there was no resisting the thought that they would have been better off if that heat had been retained.

While the single-board flat cover has so many advantages that I hardly think I shall ever be willing to go back to the covers I formerly had, still there is no denying the real disadvantages in the flat cover. First, it is cold; second, it warps and twists so that it doesn't make a close fit. Before I had flat covers, if a hive stood out with snow over it, that snow melted away very little faster than the snow on the ground. A quilt or cushion was over the frames, then a space of from one to six inches between that and the cover, so that practically there was a non-conductor over the bees.

Admitting that, when snow is on the hives, it is to some extent bad to have a single board over the bees, the question arises whether that matters particularly when no snow is on them, as when in the cellar or under a shed, or even when a board is laid over the cover. Is it any worse to have a single board on top than at the sides and ends of the hive?

When my hives are in the cellar I have sometimes looked in at the entrance, holding a light there, and I could plainly see water standing in drops on the back wall of the hive. If water is on the back wall, I see no reason why it will not at the same time be on all four walls and also on the cover. Is it any worse for it to be on the cover than on the walls? I can hardly see that water standing on the cover is any worse than water standing on the walls. But when it accumulates to such an extent that it no longer will stand there, then there is a decided difference. The water on the walls trickles down to the bottom, while the water on the cover falls in large drops on the combs and on the cluster o .

So it rather looks as if we wanted matters so arranged that no moisture will condense over the bees, whether in cellar or out. Outdoors, with the right covering to favor it, a thick coating of frost will accumulate on the cover, thicker than on the side walls; for the tendency of the heated moisture is to rise; then when the weather moderates sufficiently, down comes a deluge on the combs and bees.

Taking in view what I have said, C. F. Muth seems quite reasonable in his contention that the only protection he wants for his bees in winter is on top. And isn't it just possible that the great advantage claimed in some cases for absorbent cushions over the bees lay not in the fact that the materials used were good absorbents, but that they were poor conductors of heat, hence materials that would not become cold enough for moisture to condense upon?

The other trouble with the flat cover is a bad one for both winter and summer. Some seem to think that, with a cleat on each end of the

cover, it will stay straight. But a board can twist, no matter if an iron cleat be immovably fixed on each end, and with any ordinary cleat there is likely to be some turning up at the sides. The Higginsville cover is an improvement in two directions. It is not likely to twist, for the two pieces will seldom if ever agree to twist together. The edges are not likely to curl up, for the cover is thinned down at its edges, and, being thinner, is more easily held in place.

But the Higginsville cover still has the objection of the single board so far as warmth is concerned. And now I have a confession to make. Until after I had written the preceding paragraph I had not read carefully enough the description of the "ventilated gable" cover on page 911 to notice that a flat board fitted directly down upon the hive. Indeed, I had not noticed that there was any thing about the cover that was especially different from covers already in use. After reading carefully the description, and after looking at the picture for some time, and thinking it over closely, I confess it's a good cover—in some respects, better than any thing else I've ever seen.

But the advantages of the Higginsville cover I'm hardly willing to give up. With that I can carry my hives into the cellar and pile them up four or five high. How could I do that with the gable cover? That one item condemns the gable cover for my use. For those who leave hives on the summer stand, there may not be the same objection. But a large number—a number that I think is on the increase—winter in cellar, and the question arises whether you can not combine the advantages of the two covers.

For perhaps more than a year—at least ever since I first saw the Higginsville cover—I've had in mind a cover much like the Higginsville, only having a thin board or boards nailed on the under side, leaving a half-inch space between the upper and under cover. I suspect that that half inch space would be about as good as a space of several inches. That would leave a cover that would take little room (you see, the room taken up by the gable cover would be decidedly objectionable in the cellar, even if it could be piled), and it would pile up as easily as any flat cover.

While I don't feel sure about it, I don't think I want any ventilating space between the two parts of the cover. In mild climates I should think it a good thing, and possibly it may be best anywhere; but it seems to me we don't want any thing but a dead-air space so as to keep it warmer. But it would be a mere trifle to put in a strip on each side to close the ventilation.

Another item I don't like, and after using it I like it less; viz., the cleat projecting below the under surface of the cover. It hinders rapid placing of the covers on the hives; and if cleats

are put on the ends of hives for handles, the covers must be made about two inches longer. I agree with H. R. Boardman, that cleats for handles are indispensable, and the cover must conform. It will be an easy matter to nail the thin board under the Higginsville cover, leaving a perfectly flat surface to fit on the hive. That done, and the space made a "dead-air" space, I think my ideal of a cover would be reached.

I don't think I shall ever again get a new cover made of a single board, nor one made of two boards with the joint closed by a piece of tin folded and slid into saw-kerfs. Some of these days, if I live, I shall want some new covers. I want them to fit down close, so there shall be no crack between cover and hive, or between cover and super, and I think either of the covers on page 911 will fill the bill in that direction. I want the advantage of the air-space, and I want at the same time the advantage of the flat cover. What do you think of my ideal?

Marengo, Ill.

[Regarding C. F. Muth's contention that the only protection he wants for his bees on top, I might say he may be all right for his locality; but it would be hardly enough in our climate, or where it is colder, as in Marengo and in many parts of Canada. I remember one time when we were going to the Bee-keepers' Congress in New Orleans (February, 1885) we left Medina in the morning when the thermometer registered 10° below zero, and had been at that point for about a week. Snow was on the ground to a considerable depth. Well, in about four hours the train brought us to Cincinnati. There was very little snow there, and what there was to be seen was melting; and I was told that the thermometer had hardly been down to freezing for a week. Now, this is a difference in temperature that is often found between the northern part of even one State and the southern; so it will be apparent, I think, that top protection would not be enough for the northern part of the State, while it might answer for the southern part very well.]

Our ventilating cover was made for hot climates, and to take the place of the 20-lb. stone and shade-board in other climates. The two open side spaces can easily be closed up with two narrow strips, and we shall then have, practically, a cover with a dead-air space.

You id ¹ of making the Higginsville cover double is good, and it is very possible that we ought to hold ourselves in position to furnish the trade such a style whenever they call for it. But I would insist that the lower cover-boards be let into a groove, for I would never trust nails alone to hold the boards. And that brings us to the question as to whether we shall let the cleats project down on the under side. A good deal depends upon what sort of cover one is used to. Here at the Home of the Honey-bees we have used the flat covers with a cleat projecting over at each end, and would not have them any other way. You will remember that the sides of the hives are $\frac{3}{4}$ thick at the top. The ends at the top, by reason of the rabbets, are only $\frac{3}{8}$. The cleats of the cover project down and protect this $\frac{3}{8}$ —that is, they prevent the water from beating or seeping in. Another thing, the down-projecting cleats permit of grooves that will hold the boards securely. To make the covers entirely flat on the under side makes the groove a rabbet, and then nails have to do the whole work of holding the boards.

Yes, sir; there is a good deal in getting used to a thing. If you can get used to the cleats projecting downward, and can be convinced that they make a better and stronger cover, then why not get used to an arrangement that may appear to be a little awkward at first?

Yes, I know you prefer cleats nailed on to the hives in lieu of handholes; but here again is the old saw, "getting used to a thing." The handholes for the last year are not the small scrumpy things that they once were. They are made wider and deeper; and I do not know but they can be made wider yet, so as to give the same handhole grip, practically, that you obtain from the hive-cleat, without its awkwardness.—ED.]

HIVE-COVERS.

THE TORONTO CONVENTION AND HONEY-BEE CONCERT.

By F. A. Gemmill.

There are two items of particular interest to me in GLEANINGS for Dec. 1 that I desire to call attention to. As, however, I do not wish to write a long article on either one of them, I will endeavor to be brief and give them in the order as per the above heading. First of all is the illustrated gable ventilated hive-cover and your comments thereon. I fully agree with you respecting the "20-pounder," as I have used it, as well as the shade-board. I do not, however, use a quilt in summer when producing comb honey, and seldom for any purpose except when feeding small quantities of thin syrup or honey for stimulative purposes between fruit-bloom and clover, and for winter covering under the packing. The latter plan I am to some extent discarding, finding them not an actual necessity when the other conditions are satisfactory; and as for enamel cloths, I never used even a single one for experiment. My flat wooden covers all have the requisite bee-space under them; consequently, for the reasons you advance, the quilts are not at all necessary, whether or not producing comb or extracted honey. I have, therefore, concluded to give the new covers a trial, in the hope that some labor and time may be saved, without altogether sacrificing the needed protection from the hot sun, etc.

THE TORONTO CONVENTION.

Like Mr. McKnight, I am also glad that Toronto has been chosen as the next place of meeting of the International convention; and as that gentleman has given your readers his views so well, it is needless for me to attempt to add any thing more in this direction. I trust, notwithstanding this, that Americans or Canadians (Yankees or Canucks), will be carried away with the idea that no other convention of importance is to be held in Canada during the coming year of 1895, as the Ontario Bee-keepers' Association is to meet in my city (Stratford), Jan. 22, 23, 24; and although we have had some excellent meetings of this asso-

ciation in Canada, we expect the coming one to eclipse all former ones. If it does not do so it will be a disappointment to those who have the matter in hand.

For the benefit of those who desire to attend, I may say that our railway facilities are unsurpassed by any other point in Ontario. Numerous trains arrive daily from the east, west, north, and south; and for a city of its size the hotel accommodation can not be excelled. The court-house, for holding the regular sessions, is not only commodious but central as well. Having stated this much, I want specially to bring before the notice of the readers of GLEANINGS that a new departure is going to be attempted, which, I am quite satisfied, will be an improvement; and as it may possibly be looked upon by some as one of my hobbies, I am the more eager that it be successfully carried out on this occasion, as several attempts at my request, in other places, did not meet my anticipations. As a natural consequence, I am in hearty coöperation with a few others in endeavoring to see my scheme materialize. It is, in fact, nothing short of a public entertainment to be held on one of the evenings, while the association is convened in this city, for the special benefit of the public, so that they may be educated or instructed in regard to the value of honey as a food, accompanied with a magic-lantern exposé, and lecture on the anatomy of the honey-bee, illustrating at the same time the manner in which the insects fertilize the flowers, secrete wax, build comb, gather and ripen honey, etc., interspersed with both vocal and instrumental music suitable for such an occasion.

We Canadians are not going to be behind the times; and as Dr. Miller on one occasion in *Stray Straws* referred to "a man up in Canada" as advocating a honey-bee concert, we want him up here to see how we do things, and then he will know all about it, and can do likewise; but then, he is not going to be allowed to do or say any thing except "I don't know nothing," or something like that. But in case he might be offended, I'll show him *up* in my apiary, as I have his name painted on a beehive, in good company with some prominent German, French, American, and Canadian apiarists, who, I guess, will "kinder" smooth him over, and he will then feel at home, even if among good "basswood" honey-producers. Of course, it is generally conceded by Canadians that, in the matter of basswood hams and wooden nutmegs, the Americans, or, if you please, the citizens of the United States, take the cake.

Stratford, Ont., Dec. 11.

[Your scheme for the next Toronto convention is an excellent one, and we shall be glad to boost and boom it in GLEANINGS, in every way possible. Our conventions might do us vastly more good if we would make them more a

medium for conveying knowledge to the general public of how the "bees make honey," and that it can be produced by the car and train load, and every drop of it be pure honey. The magic-lantern exhibition would help wonderfully. Then while we are about it, let us not forget to get the newspapers all over the land to give full reports. Without any thought of flattery, I believe I am safe in saying the bee-keepers of Ontario will do more along these lines than those in any one State of our Union.—Ed.]

ONE POINT IN WHICH THE FLAT COVER IS SUPERIOR TO THE HIGGINSVILLE.

Allow me to suggest one point in which the flat cover is superior to the *Higginsville*. When I first saw the flat cover with grooved cleats I took a strong fancy to it because it was so plain, simple, and perfectly *reversible*. For 15 years I have had experience (generally unpleasant) with an almost endless variety of covers. I have yet to see one that will not warp. With the flat cover to remedy this condition, you have simply to turn it over. Please answer me one question: Is not the *Higginsville* a cheaper cover?
C. A. MONTAGUE.

Sang Run, Md., Dec. 15.

[Nearly all our flat covers in use have been reversed at some time, as the propolis-marks show, but the reversing was accidental rather than for a purpose; but a single-board cover, if it has any tendency to warp at all, warps, or tries to, so far as the cleats will permit, all one way. Much will depend upon how far the board was from the heart of the tree. The *Higginsville* model, besides the cleats and gable strip, is made up of *two* boards; and theory as well as practice shows that the warping tendency of the one will correct that of the other. But another important point is, that the outside edges of the boards are brought to a thinner edge, and this weakens the curving tendency so that the cleats will be able to hold them.]

No, the *Higginsville* cover is not cheaper for the eight-frame hive. It would be for the twelve-frame size, because wide boards for such a size would be expensive.—Ed.]

RAMBLE 123.

IN THE SALINAS VALLEY.

By *Rambler*.

We made our quiet entry into the town of Paso Robles on the 19th of July. They never have any hot weather in Paso Robles; but the day we entered, and the next day, which we passed there to give our lame pony a rest, and to wait for our mail, the thermometer registered 96° in the shade. We perspired a little, though we were camped under one of the oaks near the great hotel. The hot sulphur springs make the town noted; and many who are afflicted with disease come here in quest of health. Three miles from town is the Santa Ysabel sulphur lake, where open-air bathing, mud baths, and boating, are indulged in. These attractions, and the beautiful drives around the country, bring not only invalids but tourists to town, and it has on the whole quite a prosperous air.

From Paso Robles to San Miguel (St. Michael) would ordinarily be but a two hours' drive; but with our lame pony we were half a day getting there; and while our ponies were eating their allowance I strolled over to the Old Mission, which is located here, and photographed it from various points. Much of it is in ruins. A kind padre, however, has it in charge, and is willing to receive the little stipend the visitor is willing to offer. In fact, there is a notice on the door, saying that a two-bit piece dropped into the slot would be a welcome visitor. There was not a very prosperous air around San Miguel. The country was parched to such a degree of dryness that no crops had been secured; and the few people loitering around the streets had a discouraged aspect. I learned, from what I considered a reliable source, that there were two extensive bee-keepers near San Miguel. After diligent inquiries at the stores, the livery stable, and of our friend the blacksmith, I could learn nothing of Messrs. Swenson or Littlejohn, and concluded they were either a myth or had dried up with the rest of the country. I did learn there was a Ward bee-ranch out a few miles on the road we were to travel. Our afternoon journey carried us past it, and we did indeed find the Ward apiary, dried up and partly blown away, or, at least, it was the nearest approach to a deserted bee-ranch that we had seen for many days. Mr. Wilder and I came to the conclusion that our informant must have been in error, and that there were no bee-keepers in that dry country, any way. For over fifty miles we saw not a flower for a bee to work upon, and not a bee to work upon a flower.

Our drive for a couple of days was monotonous enough, and our camps windy and dusty. Saturday evening, July 21, we were glad to encamp on clean grass-covered ground, upon the banks of the San Antonio Creek. We camped, and rested over Sunday, and scraped the dust from our bodies in the crystal waters. The weather was so fine, and trees so protective, we dispensed with the tent and slept in the open air. Monday morning found us much refreshed for the continuation of our journey. Reina's lameness began to mend a little, so that we could indulge in a trot occasionally. On the creek-bottom we found a few plants which looked like what we used to call, back east, "queen of the meadow," and there we found a few bees at work.

Just as we entered the road, for the pursuance of our journey, a lone horseman came along, and, like all sociable travelers, we fell into conversation, and found that our horseman was an ex-cowboy from Nevada; had just come from a prospecting-tour on the Mojave Desert; had earned some money recently, in the capacity of a vaquero, but had "blown it in," as he termed it, in Bakersfield; was now on his way to Monterey to secure a job on the new railroad; was about dead broke, and would like

to travel along with us. We, of course, had no objections, and the ex-vaquero became an attachment to our outfit, or a sort of tail to our

OUR VAQUERO OUTRIDER.

kite. His horse was not a fiery steed, but he was honest; his ears seemed to have been broken down some time at the base, and had the habit of flopping up and down like a saturated dish-cloth. Our vaquero, too, held his bridle hand high, and allowed the motion of his hand to keep time with the horse's ears. On the whole, our vaquero was a young man of many accomplishments; and around our campfire evenings he gave us much information in relation to life on the plains.

Near Jolon (*Jo-lone*) we crossed the line into Monterey Co., and now, after several days' drive over a dry and dusty country, we enter the mountains and cross over into the Salinas River country. The change is agreeable; and Mr. Wilder, finding signs of deer, rode for several miles with rifle in hand, ready for execution upon whatever animal might appear.

WILDER SCENTS DEER; A GAME CALF.

At the foot of the grade, just as we were about to strike into a more level country, a deer arose and looked at us from under the drooping foliage of an oak-tree. Wilder fired, of course, and the deer gave a sort of scrooch, as though hit, and then took an easy trot and disappeared in

the bushes. This was the first wild deer I had ever beheld. From Mr. Wilder's stories about deer, I had my imagination all wrought up, expecting that, when I saw a deer, it would go bounding away o'er the hills, with head, tail, and horns erect—an imposing sight; but this deer just stood and looked at us like an old cow, or until it was shot at, then moved off. Why, I have seen a two-months-old calf show much more of a gamy spirit than that. Just try to lead a stall-fed calf of the above age out to the pasture-lot, with a long rope, and if you don't find gamy qualities that will throw this lone deer into the shade, then I am no judge of animal nature.

Hearing the firing, our vaquero, who was in the rear, came dashing ahead, and rendered us good service in scouring the brush; in fact, all three of us scoured, but in vain. No deer could be found. Bro. Wilder said that a deer would sometimes carry a bullet a long distance, even if shot in a vital spot. I told him I had a fair view of the deer, and I was sure *we* hit it in the shoulder. When I said *we*, Mr. Wilder turned right off into the bushes again, and went to scouring; and again we all scoured. We didn't wish to lose that deer that *we* were sure *we* had hit. But we had to pursue our journey again, and Wilder and I didn't get over *our* bad shot at that deer for three whole days. We got out of the deer country, and could not mend matters by shooting another.

We saw here, at the juncture of the hills with the plains, a little apiary of half a dozen hives. They were set up against a fence—box hives—in squalid misery, and we thought it not worth while to interview the owner. It demonstrated, however, that there was a little portion of the country that could support bees.

We now entered a strip of country, the reputation of which we had heard of for many miles. Even before we left our southland we learned that we should find the windiest place we ever experienced when we entered the Salinas Valley. The contour of the mountain-ranges, and the valley's pointing toward the Mojave Desert, cause the wind-currents from the ocean to follow the strong tendency to fill a vacuum on the desert, caused by so much heated air rapidly rising. The air-currents reach their greatest force near King City, in the upper portion of the Salinas Valley. We found the windy stories verified; and for eight miles we faced wind, dust, and gravel stones—yes, sir! small gravel stones were hurled through the air, and were any thing but pleasant to strike the eye. Our vaquero, riding doubled up on his horse, was out of sight half of the time in the clouds of whirling dust, and even our ponies we beheld as through a mist much of the time. Teams approaching us were almost upon us before being discernible; our eyes were full of dust, and we shed tears of mud. It was a drying wind, too, and several times we all drew up

on the lee and shady side of a telegraph-pole and drank from our canteen.

We entered the country of large ranches, few and far-between houses, and few camping-places. However, we sent our vaquero ahead when we approached the next ranch, and secured permission to camp. Our faces, when we got where we could look at them, were nicely frescoed with dust; ears full, more tears of mud. On the whole it was an experience to be remembered. The Salinas River is here bottom side up as usual, and windmill water is used for the herds of stock. Every thing is usually free to the traveler on these large ranches; but they have a sort of deserted appearance this dry year—not so many men employed, and the cattle were being driven off to better pasturage.

The next day, as we pursued our journey we passed through a herd of 500 cattle in search of greener fields. All the way to Soledad we traversed a wind-swept road. It is hard to find, in many portions of California, people who will admit that their particular locality has any disagreeable features; but people here frankly admit that they have a very windy country. We cross the river at Soledad, and here it gets right side up, and shows a fine stream of water. From Soledad to Gonsales (Goan-saw-lais) the aspect of the country changes; the valley widens out, and large grain-ranches are the rule, to the exclusion of fruit. There is enough moisture here for the raising of a fair crop of grain, even in a dry year; and the warehouses were filled with sacks of grain, and piles of sacks could be seen in the fields in every direction. The people had a more hopeful expression upon their faces, and it was pleasant to see the change from the discouraged people we had seen during the past hundred miles. Our vaquero hustled for a job at every grain-ranch; and as he rode into a field where a steam-thrasher was at work he bade us good-by. The flopping ears of his steed flopped us a last farewell, and we entered the town of Salinas, and sojourned for a couple of days.

PINEAPPLES.

HOW USED; THEIR BENEFICIAL EFFECTS, ETC.

By O. O. Poppleton.

Friend Root:—Some time ago I promised to tell your readers something about the use of pineapples. They are a purely tropical fruit—that is, they can not stand any frost at all, without serious injury. For that reason their culture has never been attempted in this country on a large scale until within a few years, or since extreme South Florida has begun to be settled; and even here their culture is confined to such localities as are practically frost-proof by reason of water protection, such as we have

here on the St. Lucie River and other places, or high ground, as on the Indian River, near us. By far the largest part of all pineapples raised in Florida come from the lower Indian River country, within 25 miles from where I am now writing—upward of 60,000 crates, or about 400 carloads, having been shipped this season from the East Coast of Florida.

An article descriptive of pineapple culture might be interesting to many of your readers; but it would be interesting only, and not of practical value.

At first we were not strongly impressed with the value of this fruit for common every-day use in the family; but it seems to be a fruit that grows in estimation. We are now inclined to rank it as very nearly if not quite equal to the orange as a standard all-round fruit.

There are a number of ways of using the fruit. Probably the best way, as well as the healthiest, is simply to select a well-ripened apple; peel; dig out eyes with a sharp-pointed knife, and eat it fresh out of hand, the same as we do apples. Some prefer to use salt on them, the same as we do on muskmelons.

Our favorite way is to serve as sauce at the table, exactly as we would strawberries. They make excellent pies when made exactly the same as are green-apple pies, which they resemble some in flavor, but are better. Good marmalade is also made of them. There are other ways of serving the fruit, but these are our ways. In slicing pines for use as sauce, the best way is, after they are peeled, to slice them lengthwise to the core, but not through it, about $\frac{1}{2}$ inch apart; then cut similar slices around the fruit. Then cutting off the sides of the fruit leaves it all in very small pieces with little labor.

Some two or three years ago we saw an item in a paper, calling attention to the value of fresh pineapple juice in its action on tough meats. We Floridians have a corner on tough beef, so we tested the statement. Wife sprinkled a couple of tablespoonfuls of fresh juice on about 1 lb. of very tough steak, let it stand a few minutes, then cooked. The result was marvelous to us. The steak was tender and sweet, and some of it was actually cut into meal. We are told that pineapple juice is the active agent in the manufacture of beef meal, and our own experiment shows that it could be. We are also told that the juice is the best known agent for the cure of croup and diphtheria, its action on the diseased membranes being the same as on dead flesh. Fortunately, we here in Florida can not test that statement.

Of course, it is easy to test the action of any thing on articles of food before either is taken into the stomach, but not so easy afterward. Theory says the action would be somewhat alike in both cases, and experience seems to sustain that theory. We ourselves have never

tested the matter thoroughly enough to know what are the real facts; but we think we feel better, generally, when using the fruit freely. Many others think the same way.

The pastor of our church here tells me that he is troubled very much with dyspepsia, causing severe constipation. He has never yet found any thing, either medicines or food, that relieves his trouble as thoroughly as does the eating of a pineapple; and it leaves no bad effect whatever. His experience is almost identical with your own, as given in June 1st GLEANINGS, only his experience covers a year or more, instead of only a few times, as yours did.

One of our neighbors manufactures in large quantities a medicine which he calls "Pineapple Digestor." The process is a secret; but it contains considerable alcohol, and is, therefore, very different from fresh juice. I have never seen or tested the medicine. I don't believe much in alcoholic preparations anyhow; but I hear it well spoken of by some, while others think differently, as is always the case with all medicines.

Unquestionably, pineapples or their juice produces much better effect when used perfectly fresh, without boiling, cooking, fermenting, or in connection with any thing else like salt or sugar. Every departure from nature's simplest way of using the fruit injures its good effect. On the other hand, no other kind of fruit is as injurious if eaten after it has commenced to decay ever so slightly. All portions of a pineapple need to be thoroughly cut out that show the least signs of decay. I can not emphasize this point too strongly.

We have but few unsalable pineapples to work up into juice, the proportion of culls and poor fruit being much less than with oranges. Of course, there is always some fruit not as salable as the rest, and some juice could be obtained from these. It should be used fresh, unfermented, unboiled, and unsweetened; and I do not know of any method of putting such juice on the market at a low price. I know a way of preserving the juice all right, but it is more expensive than it ought to be, because it has to be bottled the same as beer is, and shipped in bottles from here. I am testing the method in a limited way this fall. If successful I will experiment still more largely next summer, with a possible view of putting fresh juice on the market; but I am afraid its having to be bottled will defeat its general use. A neighbor within a few miles of here is putting it up largely in barrels; but he preserves it by the use of large quantities of sugar, which materially injures its value for the use you wish it for. I will try to keep you posted on my success or failure in keeping it fresh, and unmixed with sugar or any thing else.

Potsdam, Fla.

NOTES OF BICYCLE TRAVEL.

AT E. FRANCE'S.

By E. R. Root.

Saturday night found me pushing my wheel up through the streets of Platteville, after dark. Not desiring to intrude myself unexpectedly on the family of E. France, I made for the best hotel. The next morning, Sunday, I inquired what church of the place the France family were in the habit of attending. I was told that it was the Methodist, and that usually one or more of them were there.

In the meantime I brushed myself up, blacked my shoes, and tried to make myself half way civilized in appearance, even if rigged in the garb of a cyclist, with clothes more or less soiled by the dust of the road and perspiration of the body.

At the church I was surprised to meet as ushers the hotel clerk and proprietor. They gave me a seat, and told me that they would inform me if the France people came in; but they did not come, as I afterward learned, owing to sickness in the family. But I had the pleasure of listening to an excellent sermon.

Well, after Sabbath-school I went to the hotel and wheeled thence to the France home, and was met at the door by the senior France. On explaining my identity he seemed a little surprised, and wanted to know why I did not come on my first arrival. He rather thought I ought to be "whipped" for going to a hotel; but I told him I thought it was hardly the thing for me to go unexpectedly into the homes of bee-keepers at all hours of the day and night, for, necessarily, a wheelman can not make any regular appointments.

As the senior France was not feeling very well, his son, N. E., and I took a stroll over the place. Before I go further, let me introduce you to him.

The junior France, now aged 37 years, takes care of the out-yards and manages the help generally, while his father, owing to his age (70), confines himself to the work of the home yard. Like him, the junior France is a man of intelligence and forethought, and, as nearly as I could judge, he is full of business and push. During the fall and winter, when he can not carry on active operations in the apiary and fruit-farm, he teaches school; and thus, I imagine, he finds his time pretty well taken up during nearly all of the year. He has taught thus for ten years, and this is evidence enough that his services are appreciated. He was three years president of the Southwestern Bee-keepers' Association—one that is really more active in its general work than the State Association. He was also president one year of the Platteville Horticultural Society, and has served in various capacities as secretary of these and other organizations. Like another prominent

bee-keeper (H. R. Boardman), he is a practical taxidermist, having had 18 years' experience. I am sorry that I can not tell you more about him; but he was so modest that I had to pick up what I could. But I can assure you that, like his father, he is one of the bright intelligent bee-keepers of the land; but as he has left the apicultural writings wholly to his father, less has been known of him. It is no disparagement to the senior France to say that the junior partner is now the active bee-keeper of the firm of E. France & Son.

You will remember that, on this same trip, I found that M. H. Hunt and R. L. Taylor were making a great success in growing fruit; but I doubt whether there are any bee-keepers who carry on fruit-growing any more extensively

and a little further on still another. At no one point was there the appearance of a very large establishment; but an hour's walk shows that they have an immense plant—one that turns out about a carload of powder every day. I believe it is the second largest in the United States.

As I was going along one of the walks leading from one mill to another, Mr. France told me that all the employes had to wear shoes furnished by the company—that it would never do to have any steel nails in the soles as in ordinary shoes. Indeed, the rails forming the track of the small railway running from one mill to another (the car drawn by a mule) is made of copper. It is not safe to have steel or iron come in contact with itself. As I approached the door of one mill (every thing was shut down, of course) a kind of nervous fear took possession of me. I remembered that I had steel nails in my shoes, and the thought came to me, "What, what if I should blow up one of the mills with those steel nails! and how would it look to our readers to hear that I, although in good company, had been blown to atoms here on *Sunday*?" When Mr. France showed me where this mill and the other had blown up, and the terrible destruction that had followed in its wake—of the great timbers that had been reduced to kindling-wood, I felt a strong desire to get away.

Notwithstanding the great danger to the employes, and the fact that working over the powder is very destructive to health, the men keep at the business until they can do nothing else, and death soon overtakes them—not necessarily a violent one, but of slow degrees; and as soon as one is gone there are plenty of applicants for the position.

The following Monday morning I accompanied E. France and son out into the home yard, and there we talked over their methods of management. As Mr. France has himself described this in the article on page 932 so fully, I shall not need to repeat it here.

I had a great curiosity to see those great shot-tower hives. Indeed, they must have been of the appearance of shot-towers when they were made up of two stories, for the frames themselves, of the standing sort, and spaced with nails, are about 12 x 20 inches, the long way up, and about 9 of them made a brood-nest, and formerly they had an upper story on top of this, of the same capacity. You will not be surprised when I tell you that such colonies used to yield a barrel of honey; but latterly the shot-towers have all been reduced to one story; and while Mr. N. E. France still prefers them to anything else, the senior France likes the eight-frame Langstroth better, worked in two and three stories. But whether the shot-tower or Langstroth, the hives are all of the quadruple type, to save space and to conserve heat in winter, and to render it impossible for do-

N. E. FRANCE.

than E. France & Son. They not only have an extensive fruit-ranch, but they grow the very finest and nicest varieties. Every thing gave evidence of having been systematized so that the labor of the hands was reduced to a minimum, and the headwork seemed to come from both father and son, so far as I could judge, in about equal proportions.

After sampling the various fruits, Mr. France asked me if I would not like to run over to the powder-mill, that adjoined on another lot. As I expected to go away during the next forenoon I told him I would. The mills are situated in a deep valley, or gorge; and as one enters the place he sees here a building and there another,

mestic animals or an ordinary wind from turning them over. They are what some people call "tenement" hives. Imagine a large double-walled hive divided up into four squares by $\frac{3}{4}$ boards passing at right angles in the center. The outer walls are double and packed. Thus it will be seen that it is necessary to have only two outside walls, of double thickness, for each colony; and herein, I suppose, is the economy. But for some reason or other the quadruple or tenement hives are not generally popular among bee-keepers, owing, I think, largely to their non-portability.*

The Franceses had discarded the old mouth smokers, such as they formerly used, and were using a modified type of the Bingham of their own construction. They had heard of the Crane, but had never seen it. When the senior France commenced to fill his smoker he said he had found that ordinary straw, packed tightly with a little tobacco, was about as good a fuel as he wanted. Indeed, the straw alone makes an excellent fuel. It makes a very dense white smoke—one that is pungent and powerful; and while we were looking over the bees, the smoker did not require replenishing, I think, any oftener than with planer-shavings or even blocks of wood. Of course, if the straw is not packed in tightly it will burn quickly.

The Franceses are using principally the Carniolans. They prefer them for their own use to any others. The home yard was largely of these bees, and other yards were being Carniolanized, if I may coin the expression, as rapidly as possible.

Our Platteville bee-keepers are conservative, and not inclined to adopt any new fad except on careful and thorough trial on a limited scale; and the adoption of this race of bees by the Franceses must indeed be quite a feather in the little caps of these black fellows.

We finally went into the honey-house where there were barrels, large and small; but not many of them were full of honey, owing to the short season. They find that barrels are the best packages for large amounts of honey, and, when properly coopered and cared for, afterward give but little trouble from leakage. They do not need to be waxed inside, but should become thoroughly dried, and the hoops should be driven down before filling the barrels with honey. They had had, for experiment, some large barrels made, holding 500 lbs. and over; but these were too heavy and bulky to handle. The smaller size, holding about 300 lbs., was much better. The door of the honey-house communicating with the apiary was on a level with the ground. The other door was just opposite, facing the roadway, and was just high enough so a barrel could be rolled from the floor into a wagon-box.

We next looked at the France extractor, which is of the non-reversible type. The inside reel was made of wood, for lightness and stiffness, and the whole can was put in a stout frame to hold it to the proper height for easy handling, and to protect it for hauling whenever it should be necessary. The senior France said the non-reversible would extract all the honey one could get, but the junior France expressed a desire to see the Cowan, and was beginning to feel, from the reports he had seen, that it must be quite an advantage over most of the non-reversing kind. Another year they will give one a test.

In another room in the same building was a large and fine collection of stuffed animals—some of them exceedingly rare—most of them of the junior France's preparation, and a few that E. France himself had prepared. Both of the Franceses are expert hunters, and occasionally take an outing.

CHAT ON EUROPEAN MATTERS.—NO. 3.

By Charles Norman.

Most of both the Swiss and French bee-keepers produce extracted honey. By the way, there is a honey-knife advertised, enabling one to uncap the two sides of a frame (of a certain size) without turning it. What do you think of that? Would it not, if really practical, be quite a splendid little implement? Well, Mr. Bertrand, being a bee-master, recommends, of course, the production of section honey, and gives in an article of his all the requisite directions how to proceed. He is not, however, in favor of our American square sections; first, because one might (in the super as well as in the shipping-case) place them wrong side up; and, second, because they do not correspond with the metric system, weighing only from 420 to 440 grams (or about 15 ounces) which latter argument can not well be refuted. He therefore invented and recommends what he named the "French section," which is longer than deep, measuring 130 by 105 by 50 millimeters (or about $5\frac{1}{16}$ by $4\frac{1}{8}$ by nearly 2 inches thick), weighing 500 grams, or about 18 ounces. It can be adapted to all kinds of hives.

Mr. C. P. Dadant, in the *American Bee Journal*, published two articles in which he spoke against the use of sulphuric acid for rendering wax. Mr. Bertrand has translated and reprinted both of them.

Naphthaline is asserted to be a preventive of bee-stings. A correspondent says positively that bees, when going for his "naphthalined" hands, always desist from their aim.

Concerning "laying workers," Mr. Gillet, a teacher of apiculture, has observed that, when a colony of laying workers is dumped or brushed on to the ground at some distance from their hive, the laying workers do not return, but stay

*A full detailed description, with drawing, of the shot-tower hives is given on page 369 of GLEANINGS for 1890.

in a lump on the ground. He tried, and succeeded in two ways in getting rid of "those devils of fertile workers." The first is a little more tedious. He took two frames of brood, of all ages, with the young bees from one of his best colonies, put them into an empty hive, and put the same into a dark place, to stay there for three days. On the evening of the third day he placed this nucleus, which then had five queen-cells, on the stand of the laying workers, which, in turn, were carried to the cellar. Some days afterward it was taken out again and placed at some distance from the nucleus, and the bees were brushed on to the grass. Most of them, excepting, perhaps, a thousand or more, returned to their old stand, where now and then some bees were killed, "but this was all." Those bees which remained on the grass were mercilessly destroyed. A month later he opened the hive and found a "magnificent" queen (reared in a two-frame nucleus).

The second way is less complicated. One evening he gave the same scent to the colony with the laying workers and to the weakest of his other colonies, on account of fighting. On the following day he moved the colony with the laying workers about 350 feet from their old stand, on which he set the scented weak colony, and brushed the bees off on the ground. Nearly all went back to the old stand, and there was no fighting. About 300 or 400 bees remained on the ground and were killed. Eight days after, he opened the hive and every thing was normal.

In speaking of the preservation of drones for late queen-rearing, Mr. A. I. Root, in his A B C book, says: "I believe drones have been, under such circumstances, wintered over." Well, one Mr. Cédre, relates that, after sufficient rains toward the 15th of October, the queens not only laid pretty well, but that drones had been reared, and says: "These drones, in small quantity, to be sure, have wintered over in two or three hives, and died after some flights in March. This is the first time I have observed this fact."

St. Petersburg, Fla.

DRONES, DRONE-LAYING QUEENS, AND LAYING WORKERS, USELESS.

AN INTERESTING EXPERIMENT.

By Willie Atchley.

If I remember aright, I promised the readers of GLEANINGS that I would test the value of drones from drone-laying queens and those from laying workers and unfertile queens. Now, I must recall the promise that I would try this on an island 18 miles out at sea this year, and report. As the experiment would cost me in cash \$50, not counting time, I had to postpone the scheme till some future time. As the hot July wind very nearly ruined our nu-

clei, we had to use all the means we had to restock our queen-rearing business, and had no money to spare for the proposed experiment. But as we have places here on the prairie where we can get five or more miles away from bees, timber, or anybody, we tried the experiment in a small way. While this could not be taken conclusively, I am now fully convinced that I do not want any of my queens mated with any but drones from best fertilized queens. We are satisfied that nearly all, if not all, the queens put on the prairie were mated with the drones from laying workers; and while they seem to be just as prolific as any queens, they are ruined by being mated with these undeveloped drones. What I mean by undeveloped drones is this: drones from any but good fertilized and laying queens, as we all know that a queen is not thoroughly developed till she is mated and begins to lay. Then a drone from any other source is from an undeveloped mother, and is an undeveloped drone.

Now, our experiment queens would mate and lay as well as any queens, so far as we could see, in worker-cells, and nearly all the eggs would produce drones. My idea is, that the mating of these queens by such drones was so feeble that not one egg in twenty would touch the fluid and be transformed from a drone to a worker egg, as the fluid is so scant, and the vessel containing the same is not full enough, and the eggs pass right on by without being impregnated, and all caused from improper mating.

I am now of the opinion that weakness, either in the queen or drone, will cause a defect in the mating, and a drone-laying queen will be the result. I believe that a queen can be fertilized by an undeveloped drone, and yet no worker eggs be laid, as the fluid deposited by the drone is so small that the duct that conveys the eggs is not touched at all by the fluid from the drone, just the same as an egg deposited in a drone-cell for a drone; still, nature may be satisfied to such an extent that the queen may think she is depositing worker eggs. I have now come to the conclusion that I shall never allow any but drones from my best queens to fly near my queen-yards, for I believe it will sooner or later prove very damaging. I am perfectly satisfied that the queen has the power to deposit eggs without having them come in contact with the semen, or fluid deposited by the drone, and *all* such produce drones.

I should be glad indeed to have some of the old heads take this thing in hand, say Doolittle or Prof. Cook, and see if I am not right. I do believe that we as bee-keepers are standing in our own light, and sleeping over our rights, not to have this thing put through and settled beyond a doubt, as poor mating is *always* a loss to the bee-keeper. We had arranged to have some of these drone-laying queens dissected and thoroughly examined by Dr. Howard, at

Dallas, during the fair; but professional duties kept him, and nothing was done.

Now, who will volunteer to take up this matter with me next season? and how many would be willing to throw in a dollar to have this all tried 18 miles out in the ocean, so that answers to such puzzling questions could be answered beyond a doubt?

Beeville, Tex.

[Here is \$5.00 from GLEANINGS.—ED.]

SOME KINDLY HINTS TO YOUNG WOMEN.

ESPECIALLY THOSE WHO ARE AMBITIOUS TO LEAVE THE COUNTRY AND FIND A PLACE IN THE CITY.

By Mrs. N. L. Stow.

Mr. Root:—I was very much interested in Rev. W. T. Elsing's letter in Nov. 1st GLEANINGS, particularly as I know his sister, who is a resident of this city, and who, years ago, was for awhile a member of my own family. I am sure he is well fitted to lend a helping hand, and give an encouraging word, to all who are struggling for better things. I would take his last paragraph, and, with a slight change, would say, "My advice to all young women is, to let well enough alone. If you have a rich uncle or good friend who will give you assistance, well and good; if not, stay at home and learn to take care of bees," if you have not something better. I do wish I could impress the truth on the hearts of all young girls, of the fearful risk they run in coming to a great city, alone and unprotected. It is pitiful. It is wicked to allow it; and yet they are coming every day. I am acquainted with the workings of that helping hand in Chicago that is watching for and taking hold of such if possible, and starting them right, or looking for them and pulling them out of the mire, if they have fallen, and setting them on their feet again, or sending them back to the home they never should have so ignorantly left. It is called the Anchorage Mission, and a wonderful work it is doing. Near my own home there is an institution for the rescue of homeless and helpless girls—the Illinois Industrial School for Girls. My husband has conducted a Sunday-school for them for over fourteen years, so we know much of what life is for friendless girls; and, knowing it, I would plead that parents do not let their daughters go from home to earn their own living—at least, not to cities; for where one may succeed, many more wear out their lives trying to make both ends meet, or, worse still, blindly fall into the trap of the evil one. Girls of to-day are restless and ambitious;

rightly or wrongly so, as you will, women are becoming more and more independent; you can not help it any more than you can stop the march of reform in all the phases of life; but you may lead and guide them aright. If you are a bee-keeper you can get your daughters interested in your work, and have them help you, and be very sure to give them their pay or their share of the profits, the same as you would any one else. Let them have periodicals, and encourage their little ambitions, and you will, together with them, be lifted up into something better. Surely farmers who are spending their lives trying to make something grow should see to it that their own lives, and those of their families be not dwarfed.

How many parents fail to pluck the fruits of peace and joy from their family life because they have neglected to prune and train and develop the growing minds given into their charge! Surely life is more than living, and he who lives the larger life lives most.

Evanston, Ill., Nov. 30.

Friend Ernest:—In your illustration of Dec. 1, page 908, providing, as I think is the case, the

tenons are square, or nearly so, I can't see why the lowest nail in the "right way" wouldn't split the wood just as quickly as the nail in the "wrong way." You surely will admit that the

nail in the wrong way will hold far better. As you may have guessed, I made those hives, and I can't think they are so awful bad.

Chicago, Ill., Dec. 5.

C. C. MILLER, JR.

The following is the reply:

Reverting to the cut on page 908 of GLEANINGS, of the right and wrong way of nailing, I would say that the lowest nail of the former should not have shown. The cut as now reproduced is as it should be. You will readily see that the other nails put in the "right way" can not split, because each tenon is held on each side by its neighbors. No, I can not quite admit that the nails put in the "wrong way" would hold far better," for the very reason that the two boards are not held together by the drawing power of the nails. All nails, especially cut nails, and cement-coated wire nails, such as we use, have considerable drawing power, as you may know, and the strength of the corner depends largely upon how *tightly* the tenons are drawn into their places. You may drive the dovetailed corners as tightly as you can; but without the hugging power of the nails driven through the tenon into the end of

the other board, they will spring out a little. When you nail up the wrong way, the drawing power is the wrong way; or, at least, it does not restore the tenons to the tight contact that existed under the blows of the hammer while the dovetails were being pounded together.

Perhaps I can not explain to you theoretically why there is a difference; but there is a difference in practice, for we have tried both ways in our shop. While I do not wish at all to criticise your nailing, I observed that, where the nails were put through as they should be at the center of the boards, they drew the board up tight at that point; but near the outside edges there was a slight gap on nearly all that I examined, and now and then a split tenon.

I see now that I did not make myself entirely clear, and did not emphasize the most important feature; namely, the drawing power when the nails are put in the "right way."—Ed.]

RAISING QUEENS.

Question.—I attempted twice to raise queens over zinc excluders, according to your book, tiering up until queen-cells were started to get royal jelly, which was put into cell-cups, and larvæ transferred into these; but the bees refused to accept them. In looking a day or two afterward I found in both cases that the bees had removed the larvæ and royal jelly, and had slightly rounded the edges of the cell-cups. Every thing was done according to directions to the best of my ability. Where does the fault lie—with me or the bees?

Answer.—It is a singular fact that about one out of every fifty who try the plan of rearing queens as given in my book make an entire failure of it. Of the other 49 who try, forty report a perfect success, while the other nine are puzzled and perplexed over their not being able to do better than to secure from one to three perfect queens out of every lot of cell-cups tried. But while this is so, there is one thing worth mentioning, which is, that the longer those who have poor success try the plan the better they succeed. If I am correct, the editor of GLEANINGS had poor success when he first tried to raise queens this way, but afterward made a success of it. From the above I am compelled to say that the fault, when a failure occurs, must be in the operator, for, so far as I am aware, bees behave very much the same, whether it be in York State, Pennsylvania, Florida, Texas, California, Canada, Europe, or Australia, as I have reports of perfect success and also of failures from all the places mentioned, and from many others also. If any man or woman makes a perfect success of the plan in Pennsylvania (where the asker of the question resides), should not another make the same success providing he did *exactly* the same thing? As forty out of fifty do make a perfect

success with the plan, it would look as if those who make a partial or entire failure in the matter failed in some respect to work in all the minutiae of the matter in the same way the successful ones do. As I mistrust that more fail in the matter of the transferring of the larvæ than anywhere else, I am constrained to give the fullest possible directions in this matter. To those who have not succeeded I would say, wait about trying again till swarming-time, then take some of the queen-cells which the bees have prepared, from the hive, taking such as have plenty of royal jelly in them; and, after having removed the larvæ occupying these cells from the royal jelly, transfer larvæ from your select breeding queen to the royal jelly left just as you removed the original larvæ from it. Three days previous to this prepare a colony by removing its queen, and at the time you transfer the larvæ take all of the brood from it, giving it or allowing it to have three or four frames of honey or combs two-thirds or more filled with honey, as given in one of the earlier chapters of my book. Now place these cells on a stick by dipping the bases in melted wax, or stick them on the sides of the combs already in the hive, *a la* Willie Atchley, when you will place them in this queenless and broodless colony for perfecting. If this is a success you may know that there is no trouble on your part in the transferring process; but should it not prove successful you may rest assured that you killed the larvæ in some way in manipulating them; for a queenless and broodless colony, fixed as above described, will raise a queen from any eggs or larvæ which have any vitality in them. If you succeed here, try the same natural cells in the upper story of a tiered-up colony; and, if I am not greatly mistaken, you will succeed here also, unless you try in early spring or late at fall, which you can not well do if you take cells from swarming colonies. If you succeed with these swarming-cells, and can not with the cell-cups, then you may know that there is some mistake in your manipulation of the royal jelly, or else the wax used in forming the cell-cups is offensive to the bees, or not fashioned as it should be in some way. To find out which of these is the cause of failure, instead of using royal jelly, transfer the larvæ to the cell-cups by the Willie Atchley plan of removing cocoon, larvæ, and all, to the cell-cups. If you now succeed you may know that the trouble was in manipulating the jelly. If you do not then, the cell-cups are at fault. If you have made no success with any of your trials till you transferred the larvæ by means of the cocoons, then you may know that you handled the larvæ in transferring in such a way that you killed the same, and here is where you are to look for the trouble. If you think that you failed in handling the larvæ, allow me a few suggestions.

Make the point of the quill used in transfer-

ring very thin and quite broad; then give the point much curve, so it will fit the bottom of the cells nicely. Now, before trying to transfer the first larva, dip the point in royal jelly till it is thoroughly moistened with the same, when you will note that, as you pass it under the larva, said larva is floated up on this royal jelly adhering to the curved point of the quill, so that it does not touch the quill at all, so can not be injured if you use any care in setting it down in the royal jelly in the cell-cups. If you are bothered about seeing, shave the piece of comb containing the larva down almost to the septum of the comb, or base of the cells, when no one should have any difficulty in seeing perfectly who can read the print of these pages.

But perhaps you tried the plan of queen-rearing too early in the spring, or during cool weather in September or October. Or perhaps you did not feed the colony when honey was not coming in from the fields, or did not have unsealed brood in the upper story; any or all of which would tend toward a failure. If the weather is cool, and no honey coming in from the field, the bees should be fed till they are all alive and active, the same as they are when honey is coming in from the fields and at swarming time; for if we would raise good queens at any time of year these conditions should be brought about as nearly as possible.

PINE TAR FOR FEEDERS.

If Dr. Miller will take pine tar, and work in air-slaked lime, to the consistency of putty, he will find the article he asks for in "Straws," Oct. 15. As it hardens quickly it is best to mix but a small quantity at a time. For cracks in hives, leaky pails, or other articles, it is easily applied, and durable. For hive-covers of canvas, take pine tar, mixed with ocher into a soft putty; let it stand 24 hours, and thin with linseed oil to the proper consistency. After tacking the canvas around the edges of the cover, wet it thoroughly; and after the surplus water has run off, give it a good coat of the paint, which can be repeated, if necessary, with lead, if the color is objectional.

New Smyrna, Fla. JNO. Y. DETWILER.

LIST OF SUBSCRIBERS ON THE WHEEL-ROUTE.

I have recently received some back numbers of GLEANINGS, from home. I would suggest to Uncle Amos to put a list of his delinquent subscribers in his pocket when he is out on his wheel. He probably passed 602 South Metcalf ("Wapak" road) the evening he was wanting information regarding those "vast reservoirs of oil." have been making 'em for the last nine

years, and guess I could have told him "sumpin"—a' done it too—probably got permission to show him around our \$2,000,000 refinery and paraffine works; Chicago pump-station, with its pumps that have pushed an eight-inch line of water from Lima to Chicago, 210 miles; gas service, etc., sufficient to take all the time he had to spare. J. K. McCLURG.

Oil Centre, O., Nov. 26.

[My good friend M., it is not only delinquent subscribers, but subscribers of any sort, of whom I ought to have a list when I go out wheeling. I have resolved many times that I would carry one the next time; but it is not every reader of GLEANINGS who is such a devoted friend to A. I. R. as yourself and friend Matteson, of Kreidersville. Another thing, I almost always go off into regions where I did not expect to go. If I had a list of the whole State of Ohio, then I could hit them. But to get down to business, I am exceedingly obliged to you for your kind offer of services; and when we have good roads once more I am going to make a second trip for further investigations. Many thanks. A good many times, after I get home, I feel ashamed of myself to think I have been so near some old veteran and did not know it.—A. I. R.]

LEARNING TO RIDE A BICYCLE.

Seeing you are a great amateur bicyclist, could you not publish instructions for beginners? We are a family of eight, and we are all trying to learn. X. PICQUET.

Sainte Marie, Ill., Sept. 28.

[My good friends, as I learned mainly after I was over 50 years old, and made pretty hard work of it at that, at least on the start, very likely my suggestions may be of some avail. Perhaps the most important thing is to find a good place. You want level ground, tramped hard and smooth. There is no better roadway for a wheel than ground that is tramped hard and firm and smooth by many feet. Then the place should be wide enough—no stumps, trees, nor any thing to hurt you, on either side. It takes lots of room for a beginner. Lastly, the ground should be a little down hill, so the beginner will not need to exert much strength to start with. If there is plenty of grass pretty tall, each side of the path, all the better. Take the wheel to the top of the slope; hold by the handles; put your foot on the step, and ride down hill. After you have done that a few times, get on the saddle and learn to guide the wheel. After you can ride from the top of the slope to the bottom, sitting in the saddle, you can soon get your feet on the pedals. You will then need no further instruction from any one. At about this stage, however, you will want a long piece of nice level road before you, and there should be a similar place (down slope) a little distance away, where you can get on to start back to the place of starting. The best place we have around Medina is on the race-track at the fairgrounds. In this case the beginner comes around to the place of starting, and so does not get away off from his companions or his home. While in Missouri my nephew learned to ride fairly well in about two hours. The ground was very hard and smooth in their dooryard. After he had got to going, he practiced by running around the house. I think he could have ridden a mile without getting off, within two or three hours after he first tried to ride a wheel; and he had less instruction than I have given you in the above. Perhaps I may

add that he is an expert in horsemanship, and is just 21 years old. If you are over 50 it will take you longer, and you must not be discouraged if you find a few bruises when you undress to go to bed at night.

Success and best wishes to that family of eight, friend P.—A. I. K.]

MR. ALLEY says, "Give the bees a chance to rest all winter. Do not disturb them at all." This is good advice, providing you know they have been fed and have sufficient stores.

THIS seems to be a rather open winter all over the country, and it behooves every bee-keeper to see that his bees do not starve. While cold winters are severe on outdoor unprotected colonies, the bees are not as liable to rear brood or use up their stores. But during open seasons like this the very opposite is true, and colonies are lost, not by cold, but by starvation. *Later*.—Since writing this, the weather has changed to almost a blizzard this morning of the 27th.

I EXTRACT the following from the *Nebraska Queen*, a new bee-paper. It is a pretty good sample of the rest of the editorial matter:

I fear there are many swarms of bees in Nebraska that will have to be fed or they will starve before you can feed in the spring. I have heard many, of late, say their bees may starve before they will spend any more money on them. Ah, my friend! how can you talk that way? Show me what has paid the past few years that has been left to its own ways. Gentlemen, your stock would perish and die this winter if you had not economized and saved all your straw, hay, and cornstalks. Many are, to-day, wondering how their stock will get through the winter. It will be through your careful care for it.

THE following are a few brief pointers in regard to advertising, that I take from *Printers' Ink*. This is getting to be the season for advertising, and I feel sure that our advertisers, or those who expect to be with us, will profit by the suggestions. Notice particularly the last paragraph. You will see how nicely it dovetails in the editorial on page 876. It is far better to invest what money you have, in a number of small advertisements, than to put it into one big flaming one and let it stop there.

Advertising is like a carriage—its progress is impeded by getting into ruts.

A great many persons will read a short story who have not time to read a long one. Same way with an ad.

Different persons read the same thing in a different manner; hence the necessity of presenting the same subject in different ways to convince different minds.

Nails driven but half way do not fulfill an intent. Half-hearted blows in advertising are as futile. Concentrated applications alone create impressions.

Merchants should bear in mind that "selling goods below cost" is unprofitable in more ways than one. Most people think you're lying, and trade elsewhere; while those who believe you, will stay away because they don't like to trade with a fool.

A dentist could probably drive home the filling in a tooth with a single blow from a large hammer; but he does a better job, and the job lasts longer, by using a small hammer and repeating the blows. The same principle holds good in advertising.

THE CROSSES OF 5 BANDERS CROSS, BUT WELL MARKED.

THERE is one objection to the five-banded Italians that I had not thought to mention before; namely, that a cross between a queen of five-banded stock and a black drone, or a five-banded drone and a black queen, will, according to our experience, result in all of the bees showing at least three bands, and in some cases four. Now, these bees, so far as *markings* are concerned, would pass for pure Italians, because, forsooth, they show three yellow bands and more; but they are, just the same, hybrids; and this accounts for the way some of the bees of five-banded stock are so "awful" cross. They are not pure; the owner says, "They show four bands, but sting like hornets."

I do not wish to appear to discourage the business of breeding five-banders; for there are some careful breeders who run for both color and business; but the color craze has been carried so far by many of the breeders, all other qualities sink into insignificance when compared with the one thing—"lots of yellow." Color will not make prolific queens, neither will it add anything to the honey crop. On the contrary, it will detract from both.

THE SHOW OF HANDS ON THE BEE-PARALYSIS QUESTION.

THE following is the revised list of names of queen-breeders up to date who have signified their willingness to destroy the first case of bee-paralysis as soon as it appears in their yards, within 24 hours after its discovery. I am well aware that some think such a procedure unnecessary; but it will surely stamp the disease out entirely, if all queen-breeders will take pains to pursue this policy for a few years. Foul brood, I feel quite certain, can not be transmitted from the ovaries of the queen, Cheshire to the contrary; and I think all practical apiarists, and those who do not depend upon fine-spun theories, agree with me. But bee-paralysis, assuredly, can be so transmitted, and should be treated accordingly.

W. H. Laws, Lavaca, Ark.
J. P. Moore, Morgan, Ky.
J. J. Hardy, Lavonia, Ga.
F. A. Lockhart, Lake George, N. Y.
F. B. Yockey, North Washington, Pa.
H. G. Quirin, Bellevue, Ohio.
Cleveland Bros., Stammer, Miss.
G. W. Hufstедler, Clarksville, Tenn.
Leininger Bros., Ft. Jennings, O.
Jennie Atchley, Beville, Tex.

By the way, I notice by the *Apiculturist* that Mr. Alley thinks the course we are pursuing in

this matter is foolish, and that a better way, and all that is necessary, is to simply destroy the bees. He holds that "the brood, honey, and combs are not diseased."

But over against this we have the testimony of Mr. T. S. Ford and others who have experimented pretty carefully, showing that the disease is carried through the combs, or the hives, for he experimented on this very point. I grant mild measures may work very satisfactorily in the North, or in any climate like that of Mr. Alley's. We do not fear the disease north of Mason and Dixon's line. The probable consequence of its being transmitted through queens from the north when sent south is what we do fear.

When some one else says something that we agree with, we are pretty apt to say, "That's good." Well, here is something from the last *American Bee Journal* that I think is "good:"

Come to think of it, I too must take exception to the *American Bee Journal* editor regarding his conclusion concerning the editorial "we" and the individual "I"—and the more concur with Bro. Ernest Root's preference. Why? Well, I'll tell you. The "I" gives all statements a more decided, independent, and responsible force; it admits of no equivocation; it courts no excuse; it holds itself personally amenable for the utterance; it practically affirms that he is the writer—"If you have any objections to urge, I am ready to afford you satisfaction!"

Now, it is not so with the usual "we." Not only does it fail to be commendably modest, but it lacks individuality and manly grit! It nebulously suggests that others are implicated in the assertions made; it is only another way of expressing the irresponsible "they say," which phrase may or may not include half the inhabitants of a given place—a weak, cowardly intimation, too frequently protected. Of all things to me most admirable is the exhibition of manly courage of one's convictions, of placing one's self firmly, honestly, and independently before the public, ready to maintain the principles he believes to be right; courting criticism from whatsoever source, and I know of no more unflinching vowel for the purpose than a respectful "I."

EMM DEE.

HOW TO FEED IN MID-WINTER.

QUITE a number have asked how to feed their bees during mid-winter. I assume, of course, that your colonies have been neglected for some cause or other, and you now discover that they have hardly sufficient stores to carry them to spring, let alone that season, the most trying of all. In the first place, it is always better to feed in the usual manner in the fall; but when that has not been attended to, something else will have to be done now, for in this case surely the motto holds true, "Better late than never."

The best thing to give the bees is combs of sealed honey. The dry ones should be taken out and the filled ones put in their places. It might be advisable to leave one empty comb in the center, with two or more combs of filled stores on either side. But we will suppose that you have not the combs. Cakes of maple syrup answer very well when laid over the tops of the frames under the quilt. But you have

not these. Cakes of dry candy should then be used. The following are the directions given in our A B C of Bee Culture:

Into a tin sauce-pan put some granulated sugar with a little water—a very little water will do. Make it boil, and stir it; and when it is done enough to "grain" when stirred in a saucer, take it quickly from the stove. While it is "cooking," do not let the fire touch the pan, but place the pan on the stove, and there will be no danger of its burning. Cover the dining-table with some newspapers, that you may have no troublesome daubs to clean up.

To see when it is just right you can try dropping some on a saucer; and while you are at work, be sure to remember the little folks, who will doubtless take quite an interest in the proceedings, especially the baby. You can stir some until it is very white indeed for her; this will do very well for cream candy. We have formerly made our bee-candy hard and clear; but in this shape it is very apt to be sticky, unless we endanger having it burned, whereas if it is stirred we can have dry hard candy, of what would be only wax if cooled suddenly without stirring. Besides we have much more moisture in the stirred sugar candy, and we want all the moisture we can possibly have, consistent with ease in handling.

If your candy is burned, no amount of boiling will make it hard, and your best way is to use it for cooking, or feed the bees in summer weather. Burnt sugar is death to them, if fed in cold weather. You can tell when it is burned, by the smell, color, and taste. If you do not boil it enough, it will be soft and sticky in warm weather, and will be liable to drip when stored away. Perhaps you had better try a pound or two at first, while you "get your hand in." Our first experiment was with 50 lbs.; it all got "scorched" somehow.

But suppose you do not wish to bother with the candy-making. Stick candy, or any kind of candy that is not colored or adulterated, that is made from pure white sugar that is hard, would answer. The only trouble would be, it would be rather expensive compared with what you could make yourself. "Good" candy—that is, powdered sugar and honey mixed into a stiff dough, may be used; but the only objection to it is, the bees suck out the honey and let the dry grains of sugar rattle down between the combs; then there is danger of its "running" and making a dauby mess.

JOHN THORNE CALVERT.

SINCE the Home of the Honey-bees has become an incorporated company, I have thought that many of our readers would like to be introduced to our secretary and treasurer, Mr. J. T. Calvert, who, although he transacts a very considerable part of the business, is not generally known to our readers, though very many of them have read letters from here dictated by him.

Mr. Calvert was born Dec. 7, 1862, in Victoria Co., Ontario. His grandparents on both sides came from old England. He was raised on a farm at Reaboro, his old home, and educated at a country school about two miles distant; and numerous were the times when paths had to be cut through the snow across the fields. This was a good school, and Mr. Calvert made the best possible use of the privileges afforded him. Indeed, if there is any thing that will clear up a youth's head, and make him do the best work, it is to walk two miles to and fro from school.

He was soon proficient enough to pass the examination for what is known in Canada as the third-class teachers' certificate; and this means a good deal more than the ordinary certificate, so called, in this country. Later on he took a course in the Ontario Business College at Belleville, doing the work of a sixteen-weeks' course in eleven. After this he spent six weeks in Toronto in a wholesale house; and from there he came to Medina in 1881.

The year before, at home, he had become interested in bees. He obtained some queens of W. G. Russell, now of Millbrook, Can., and at about the same time a few stray copies of *GLEANINGS* fell into his hands. As a result of this a correspondence began, resulting in Mr. Calvert's coming here to work.

JOHN THORNE CALVERT.

We had previously (as we do now) received a great many applications from outside parties; and as a general thing we had told all of them that it was no use for them to apply so long as so many applicants were living at Medina. But there was *something* in John's letter that impressed A. I. R. with the fact that he was a boy of the "right sort" of stamp, stamina, and character, and so he was induced to break over his custom.

John was willing to work for small pay, that he might have the privilege of learning the business; after which he expected to go back to Canada to establish a supply-house with his brother Albert, who was then living. But John developed such a proficiency at the Home of the Honey-bees, and seemed to fit so well in the harness, that several things conspired to change his plans.

He first began work in what we call the sam-

ple-room, "tying up sticks." The following summer he took charge of the apiary while the writer was at school in Oberlin. We had a heavy queen and bee trade that year, and so our new man was pretty well initiated.

In order that he might make himself more useful he decided to take a course of studies at Oberlin, working his way along, and paying his own expenses as he could. He therefore attended school at this institution, with the writer, off and on, for four years, when ill health on the part of A. I. Root, brought on by the heavy responsibilities of the rapidly growing business, made it necessary for one of "the boys" to come home—at least for a time. I came first and began on the journal in the summer of 1885, doing what I could to lift the load here; and during the following spring John came, and in his turn began to lift the burden in the commercial department. I have said that several things conspired to change his plans. I don't know which was the most potent in inducing him to become an American citizen. I need not go into details, but in September of 1886, shortly after leaving school, he married my oldest sister, Maude.

A naturally good memory for figures and names, his general aptitude for business, that seemed to be born in him, enabled him to be a proficient clerk. First he took charge of the estimates and of the buying of the goods; and later on he assumed, practically, control of the whole commercial department, including book-keeping, buying and selling, etc. Under his management branch houses were established, and other depots for the sale of our apicultural supplies were stationed all over the United States; and while we had a very good foreign trade it continued to increase, so that the business changed from what was to a large extent local and retail to what you might call trans-continental and wholesale, although the retail business and local features of it were preserved.

Mr. Calvert makes a liberal use of both the phonograph and stenographer in his general correspondence; and right here I might say that nearly all letters relating to the commercial department come under his general supervision. He is an indefatigable worker; and his general good health, owing to his regular habits of eating and sleeping, enables him to do more business than most men.

He is not less active in his religious life. He has been intimately connected with nearly all phases of the Christian Endeavor movement. He has been president a number of times of our local church organization, and two years of the county, and is now president of the Medina Co. Sunday-school Union. He is also active as a Sunday-school teacher, and greatly interested in all work of missions.

Physically he is of medium height, rather stoutly built, of light complexion, and of pleasant face and manner.

The next day was Sunday, so I could not do very much in the way of investigating the queer surroundings of my relatives; but I was so full of questions, and some of them that would hardly keep over night, that I am afraid I did a little investigating, even on Sunday. We found a Congregational church, and a very bright, wide-awake Sunday-school. The pastor and the superintendent were on the lookout for strangers; and, in fact, the latter person, after the services were over, kindly took our horse by the bits and waylaid Mrs. Root and myself and our relatives. They took us over to his own house for dinner, in spite of the protests of the women-folks that their own dinner was awaiting them at home. Then they gave us the wonderful electric water to drink. I was thirsty enough, after my week of wheeling, to enjoy it to its fullest extent. Judge Wallis, our host, gave me much information in regard to Lebanon and its people. We finally got back home, and I was very anxious to attend a Sunday-school, about a mile away in the woods; but they told me it was too late, and that we should have to give it up. A few minutes later I caught a glimpse of some feminine apparel belonging to somebody who was evidently slipping away and in haste to get out of sight. They did not answer my questions very promptly and squarely; but I soon guessed that Mrs. H—by the way, when we were boys and girls together we used to call her "Mary," for short, and I think I shall call her Mary now. Well, Mary had slipped away and started off through the woods, to that Sunday-school. It seems she had the lesson-papers, etc., that they would need. The foot-path through the woods was a much nearer way than around the wagon-road. As soon as I could make a little change in my apparel I started after her in spite of protests. Just as I was disappearing down the lane, the young lady whom I met first the evening before, and whom I shall call May, called out and gave me some hasty directions in regard to the footpath through the woods. I smiled at their directions, thinking I was smart enough to catch up with any woman on foot before she could get out of sight. Well, I shall have to acknowledge that a *Missouri* woman was a little too much for me. Had I not listened to May's directions I might have been wandering in the wilderness up to this time for aught I know. I finally caught a glimpse of Mary just before we came out into the clearing. The schoolhouse is in the center of a circular spot right in the wilderness, and the dwarf-oaks are so dense that one looks around the circle in vain to find the way out. Judge Wallis and the minister were there before me, with a double buggy, and I laughingly asked them where in the world they got inside. The judge said he could hardly tell; but when they went home they were going to drive clear around the outside until they should come to a vacancy in the trees where they could squeeze through.

The country schoolhouse was pretty well packed with people. Mary did not know that the minister and the judge would be present, and so she felt anxious about having somebody on hand to look after the young people in case the regular leaders did not appear. The most of the gathering consisted of boys and girls, such as you might find in any neighborhood. As the pastor from town was present, we had a

short preaching service after the lesson. The discourse was taken from the forest-leaves that had just been nicely decorated by the first frost of autumn.

In almost every country neighborhood, especially where they are a little off from town, the boys and girls are always wanting to "go somewhere," especially during a Sunday afternoon in the fall of the year. Now, can any better place be devised than a Sunday-school in the schoolhouse, with a good sober spiritual man or woman to look after the young people? I often think of that pleasant walk through the woods on our return home. Thirty years ago both Mary and myself were quite intimately acquainted. But while in our teens, neither one of us, I fear, thought very much of spiritual things. What changes time had wrought! In those days gone by, a Sunday-school in the country would have been the last thing to attract my attention, unless, indeed, I went to have some fun. May God forgive me, as my memory goes back to those old times, to think that once or twice my principal motive in going was, pretty nearly, only to create disturbance. It may be well for me to think of this when I feel inclined to criticize too severely some of the young people of the present day.

Monday morning I was wide awake for investigations. The view of that great spring impressed me with the idea that the locality was cavernous, like the region around Mammoth Cave; and even before breakfast I found a low place, right in front of the house, where the waters during a heavy rain went down and out of sight. There was originally a sort of cave there; but in working the road it had gradually filled up. Furthermore, in one of Rob's fields, during harvest time one of the horses broke through and went down into an underground pit, and they had to stop work and get it out. As this pit was quite a nuisance in the middle of the field, they had filled it up with trash. When I protested, Robert told me that we should find caverns before I left, without going to the trouble of digging. Judge Wallis told me that, in drilling for that beautiful water in Lebanon, the drill several times passed through cavities, and they were obliged to tube the well through these to prevent losing the water.

Right here perhaps I may say a word in regard to the wonderful "electric water," as they term it. In the first place, if you hold a knife-blade in the stream of water as it comes out of the iron tube it will become magnetized, showing the wonderful electric properties of the water. Secondly, when this water is used for making steam, if you hold your hand in the jet of steam as it issues from a pipe, electric lights or stars will be seen on the ends of your fingers. These facts are vouchsafed for by the judge himself, for he had seen them with his own eyes. As it was Sunday, and I was his guest, I did not feel like taking him to task just then and there for the superstition; but, dear reader, let me say to you that all these stories about magnetic water are right along in line with the Electropoise swindle. The man who puts the knife-blade into the stream of water from the medical well, takes pains to draw the blade across the top of the *iron tube*; and it is this iron tube and not the water that makes the knife magnetic. Any iron tube or iron bar that has been standing awhile upright in the ground is quite sure to become magnetized. Men who drill wells are familiar with this fact. In fact, iron tubes sometimes become so strongly magnetic that they will pick up a small-sized adjustable wrench. A friend once told me that the water in a glass bottle taken from a magnetic well would magnetize a

knife-blade. He had been paying a dollar a bottle for said water, for curing rheumatism. When I told him how he had been humbugged he stopped wasting his money, and concluded it was something besides the water in the bottle that had affected his rheumatism. In regard to the sparks of electricity, if you will on any frosty night hold your hand in escaping steam from a boiler you will, if the conditions are right, see these same electrical appearances. In fact, this whole thing is mentioned in the books on electricity. But here in Lebanon they had built a great hotel, costing ever so many thousands of dollars, and put in an electric street-railway, and advertised far and near those wonderful waters of the electric well at Lebanon. Of course, visitors were shown the experiments in magnetism and electricity; and reasoning from what they saw with their own eyes they were not slow to have faith in this beautiful water with such strange properties. Some weak invalids could not stand a bath in the water, as it was so highly charged with electricity—that is, they could not until they got used to it, so it was said. Well, the proprietors of the scheme made lots of money for a time; but the hotel is now shut up and deserted. The electric-car line does not pay expenses. The water is given away to anybody who wants it. Let me say, however, that the water is remarkably pure. It is almost absolutely pure soft water, and I can readily imagine that people who do not have nice pure water at home may receive great benefit by going to Lebanon and drinking its pure water. I think, however, the benefit will be just as great if they would set some tin pans out during the latter part of any summer shower. Keep this water and store it up; or save the water during the latter part of a shower from any good *slate roof*. Store it in clean stone crocks, or have a real nice cistern, with some sort of pump that is not made of old wooden tubes or rusty iron machinery.

We soon made up a load and went to see one of the strange caverns scattered through the Ozark Mountains. Away out in the woods, almost on the summit of a good-sized hill, we found a great hole, perhaps 30 or 40 feet across. The inside of the hole had fallen out—or you might say with much truth the *bottom* had dropped out; and then away out under the side of the hill was an enormous cavern roofed with sloping rocks. At one side, by using care, one could climb down through the sand and gravel and broken stone. Inside there was nearly if not quite a quarter of an acre roofed over with limestone. Now, as this was on high land, and inside a good-sized hill at that, and during the most excessive drouth, almost, that Missouri has ever known, I hardly expected to find water; but, sure enough, we soon heard water dropping. It was dripping from the roof in different places. I soon satisfied *myself*, however, that this water did not come from water in the ground or in the rocks. It was produced by condensation. The day was quite hot and sultry outside. Well, this hot sultry air, coming in by circulation, as it struck the comparatively cold stones deposited its moisture, like dew on the side of a cold pitcher. When the drops were sufficiently large they ran together and trickled down to the lower portions of the roof of the cavern. Here they dropped off. By setting a tin cup in the right place, one could, in a little while, get a drink of pure soft water. In former times people had placed tubs (and we saw the remains of these) in order to catch this beautiful "spring water."

A few days after, we visited what is called Saltpeter Cave on the banks of the Gasconade River. There are acres of underground cav-

erns here in the cliffs beside the river. Stalactites and stalagmites are so plentiful that the dooryards all over Laclede Co. are decorated with them. Everybody who goes to the cave takes an ax and a lumber-wagon, and breaks off the icicles, some of them nearly a foot in diameter, and takes them home to place among the flower-beds in the front yard or beside the doorstep. Now, my impression is, although I have never seen the matter mentioned in works on geology, that these stalactites, etc., are formed principally by the condensation of the moisture in the atmosphere, especially during our hot summers. These cliffs are so honey-combed with caverns that warm air from the outside is continually rushing through in currents depositing its moisture on the rocky ceiling overhead, and then going back to be warmed up and charged with moisture again. Here in Saltpeter Cave, as it is called, the whole operation can be seen going on all the time. The icicles, as you might call them, are soft, and many of them feel quite greasy. The drop of water on the end is thick with minerals, sometimes almost like molasses. The currents of cold air rushing through take up the moisture, and the mineral accumulates. The strange part of it is, that, although the icicles are so soft and pasty on the tips where they are forming, and on the outsides, they are, in the center, a flinty rock. Some of the rooms in this cave are very beautiful. There are figures, and shrines and pulpits and gardens, and, in fact, one can imagine almost any thing wrought out in Nature's laboratory; and in this cave, at least, Dame Nature builds pretty fast. My friends told me that, even in a few years, great changes have been going on. I should not be surprised if these icicles grew an inch a month, or a foot a year.

There hadn't been rain for months. In fact, farmers were seen at all hours of the day, and on almost every road, driving their stock to the springs or to the larger pond-holes where the water was not yet exhausted. By the way, in some places in Missouri the only water they have to *drink* during such a season of drouth comes from these pond-holes dug in the ground. Now, in such cases is it any wonder that great cures should result by going to some celebrated spring, and putting up at an expensive hotel? Of course, the people were longing for rain. It came on the second Sunday of our visit, in the afternoon. We had been to church; but it was so rainy that the general conclusion was no one would be over to that Sunday-school in the woods. I decided once to stay at home, but I felt uneasy. Suppose just a few boys should gather there in spite of the rain, with no one for a teacher. I knew from experience that I could get through the path in the woods on my wheel, even if all the rest did say that the thing was impossible. The falling leaves kept the tires out of the mud; and as I had learned to dodge the bushes, and scorch when necessary, I got along pretty well. When I got out of the underbrush into the clearing, however, imagine my surprise at seeing a dozen or more saddle-horses hitched to the trees. Sure enough, the schoolhouse was almost as well filled as on the previous Sunday. Some of the women-folks had come a couple of miles in the rain. There was no superintendent, and nobody to take the lead. I finally volunteered; and if you will take my statement for it I should say we had a grand good time. I did not do *all* the talking either. The superintendent came in pretty late, but he refused to take my place. I did get him to talk, however; and one of his remarks I shall remember a long time. He said the greatest trouble with a good deal of our religion is that it is of a kind that will not

stand wetting. He said he hardly thought anybody would be there, but he finally decided to come. He was about to move out of the neighborhood, and here was a little flock of Missouri boys and girls in their teens, great stalwart young men of both brain and muscle, waiting, as it seemed to me, for somebody to form them into line. I took the liberty of selecting a nice young fellow for superintendent. He said he had only recently united with the church, and that somebody with more age and experience would do a great deal better. My friends, I do not agree with this kind of talk. A new swarm of bees will frequently work with double the vim, and gather ever so much more honey, than an old stock with double their numbers. Is not this true? Well, a new convert, even if he is not so familiar with the Bible, and does not know how things are usually done, will sometimes bring souls into the kingdom while one of the old deacons would be getting them into classes. No disrespect to the old deacons, however. They generally have enough to do if they keep bright and young in spirit, even if old in years. The boys were curious about my wheel. Some of them thought that, with the young Missouri horses they had there in the inclosure, they could throw gravel in my eyes where I had nothing but that little 22-lb. Victor. Well, may be they could. If I should ever have a chance to try a race with them I believe God would give me grace to rejoice and feel happy, even if they came out ahead.

I asked them about the state of temperance in their county-seat. Said I, "Boys, what on earth was it that brought the saloons back to Lebanon after you had once got them banished from your town?"

Nobody replied to my question just then; but quite a spell afterward a fine young fellow spoke up something like this:

"Mr. Root, you asked what it was, a while ago, that brought the saloons back to Lebanon, after we had once cleaned them out. I think I can tell you. It was the *love of money*."

There you have it, friends. That was a very short temperance speech; but I think it strikes at the root of the matter. Without *Christ Jesus* to drive *selfishness* out of the human heart, all schemes for temperance reform, or any other reform, in fact, *must fail*.

ROBBING SICK PEOPLE.

ELECTROPOISE UP TO THE PRESENT DATE.

Our readers will doubtless remember that I gave an extended *expose* of the Electropoise, in our issue for August 1, 1894, page 627. Some months before, I wrote it up with a caution, or warning, in our Medina paper, because agents were selling the bauble throughout our county, and because religious papers seemed to be its particular vehicle for advertising. Now, I want to confess to you that this matter has been on my mind a good deal. I felt greatly troubled to see our people, during these hard times, paying \$25.00 for a thing of no more value than a china nest-egg, and not a whit more scientific, let alone its power to cure the most difficult chronic disease; but I felt more troubled still to think that not a scientific paper—not a professor and not an electrician, so far as I knew, in the whole United States, had come forward to back me up. I wrote to the *Scientific American*, and its editor said that it was undoubtedly a fake, and that they had no faith in it; but they did not *print* a single word of warning. The boys in our machine-shop were studying electricity, and they backed me up, of course; but nobody seemed to care very much how much swindling

was done in that line. I have written to our religious papers that advertise the thing, calling them to order; but they do not seem to care, so long as they get their money; and, worst of all, men and women, who ought to know better, question my *right* to criticize. They suggested it was improbable that such prominent men would give the Electropoise such a testimonial if there were not something in it. Some of my good friends mildly suggested, too, that perhaps I did not know *quite* every thing, and may be I was not up to the times in the way of improvements. Well, a few days ago a woman was injured by an accident near our home. Mrs. Root took her in and cared for her until she was able to ride home. Before she went away, however, she said she had an Electropoise, and that it was a wonderful help. The poor woman was not able to talk very much, and so I did not get a chance to interview her; but Mrs. Root says her statement was something as follows: Before she had the Electropoise she was obliged to take great quantities of medicine in order to be up and get around. The agent who sold the thing, however, informed her that she must chop off all medicine entirely; the 'poise would not "work" where medicines were around. "Work," indeed! Well, she discarded all medicines of every sort, and confined herself to following Electropoise directions implicitly, and, strange to tell, she was very much better right away. Did you ever! And this reminds me that I want to ask you to read T. B. Terry's talk on medicines, on the next page. But now for the triumphant *expose* of the Electropoise. The following is taken from the *Western Christian Advocate*, of New York: A. I. R.

AN ELECTRO-MEDICAL FRAUD.

"*Electricity*," a scientific journal published in New York, in its issue of November 21, prints an *expose* of the "Electropoise," an extensively advertised panacea, with certificates of its effects from men in high places. It turns out, by scientific demonstration, to be the veriest cheat, achieving its magical healing through the imagination of its patrons. It claims to cure by "thermo-electric induction"—a conceit that has no scientific basis, there being no such thing known to electricians; to so polarize the body as to attract the oxygen to its surface, and diffuse it through the system. The expert affirms that "neither magnetic nor electric polarization has any effect upon the atmosphere, except to abstract from it the dust; that, if the body were polarized to a million volts, there would be no such attraction," while this "little joker" has but "one-thousandth of a volt." The proprietor alleged that the closed cylinder contained two rare metals no chemist could analyze, while there are no metals which can not be analyzed.

Electricity purchased an "Electropoise," and had its contents examined. It was found that the nickel-plated cylinder, three inches long and one inch in diameter, was filled with flowers of sulphur and graphite made into a paste and allowed to harden, which, when used, is placed in cold water to set up by moisture a chemical action, which is so small as to be insensible and capable of exerting no influence on the system whatever. In one end of the cylinder is fastened an ordinary flexible cord, the other being affixed to the metal clasp of a garter for attaching it to the wrist or ankle. Flowers of sulphur costs two cents a pound, and graphite ten cents. The cylinders can be made, in quantity, for ten cents each; the cord, two yards in length, can be had at retail for twenty-five cents; and the garter for five cents, making the whole cost forty-two cents. The 'poise is sold for \$25.

Another, a wall instrument, sold for \$50, consists of a walnut board, upon which are two multiple switches, each with six points. Two flexible cards and garters are attached, and the "polarizer" is suspended and dropped into a basin of water. Two patients can be treated at one time by each attaching a garter. One of the switches regulates the current by turning the lever to the desired point. The other switch is for disinfecting germs and destroying odors, which is electrically absurd.

The proprietor professes to have a twelve-page

type-written testimonial from the Smithsonian Institute, of its being "a scientific instrument of great value," which was proven false by correspondence with the office in Washington.

The business methods of the concern, imposing it on the public, include all the accessories of the confidence and green-goods game—the stool-pigeon, the capper, the bogus purchaser, and the office boy rushing in to borrow the only "Electropoise" on hand. *Electricity* calls on the police and postal authorities to investigate the swindle and arrest the swindlers. It says: "We denounce the 'Electropoise' an outrageous humbug, with knowledge that many intelligent people have testified to wonderful cures who rest under the suspicion of self-interest." It enumerates sixty diseases it infallibly cures, and names the *New York Sun*, the *North American Review*, and eight among the many prominent religious papers giving it space and indorsement.

The *expose* is scientific and thorough, and no candid mind can escape the conclusion that the device is void of merit, and that the "Electrolibration Company," is advisedly palming off on the afflicted a worthless nothing at an exorbitant cost to the purchaser.

The cheat ranks with the electric brushes, soles, and "Perkins Tractors," exposed by Dr. Oliver Wendell Holmes.

As a psychological imposture on the infirmities of cultured minds, it is the cutest fake of the age. We do our readers a practical service by foretelling any tempted to try this costly fraud from losing their money and execrating themselves for their credulity.

Now, friends, are you ready to give up? Is there any one among our readers who is prepared to defend Electropoise after the above *expose* thereof? I feel like saying, and I am going to say right out in print, May God be praised that we have such a scientific journal in our land as *Electricity*—one whose editors are willing to invest \$25.00 for the sake of showing up fraud and humbug! yes, even though religious journals indorse it, and United States senators, or their wives, give it the strongest kind of recommendation; yes, even though so-called *college professors*, and ministers of the gospel too, have lent their influence to help it along.

T. B. TERRY ON PATENT MEDICINES, ETC.

ALSO SOMETHING IN REGARD TO THE TREATMENT OF THE DISEASES OF DOMESTIC ANIMALS.

[The following is so much in line with the teachings of our own journal, and coming from such authority as T. B. Terry and the State Veterinarian of Missouri, we copy it entire from the *Practical Farmer* of Dec. 15.—ED.]

Before the opening hour for the Institute the other afternoon we saw a man get up on a box and collect a crowd around him, to whom he was trying to sell some so-called medicine. His audience was composed largely of farmers. Of course, he had his little game. The people were made to think that they would get their money back later on, that he was only advertising the medicine. And you ought to have seen the rush to get something for nothing. They seemed to believe that the man could pay his hotel-bills and traveling expenses, silk hat and all, just for a chance to give them something valuable. Well, they tumbled over each other in handing up their \$2 each, until \$60 or \$70 was taken from the crowd; and, owing to a "catch" in the promise, only one or two got any thing back, of course. I saw farmers without money borrow it to give to this man for something of which the best use they could possibly make was to smash at once. Now, there was in that crowd an agent for the *Practical Farmer*, who told me he had tried in vain to get a single farmer to give him \$1 for a copy for the rest of this year and during 1895. They all said times were so hard they could not afford it. This is a true picture, friends. My friend Abbott, President of the North American Bee-keepers' Association, was standing by me and watching the game. How can

we reach such men? The medicine-man is making money like every thing, and we have met him this year in many forms, and more than once he has cut down our attendance.

Dr. Turner, State Veterinarian in Missouri, was asked at one Institute about hog cholera medicine, whether it did any good or not. The doctor is a fine young man, and one of my particular friends, and I was a little anxious about the stand he might take on this question. But he came out boldly and squarely. He said: "The virtue lies chiefly in the directions, which come with the medicine, which you follow. You are told to take at once all well hogs away from the sick ones and put them in a new place, and not down stream from the old place, and to leave the sick ones right there, and to burn the dead ones, and be careful about tracking any soil from the ground where the sick ones are to the other field (feed well ones first), etc., and these directions carefully followed will stop an outbreak of hog cholera very soon." The doctor was asked if filthy pens, an exclusive corn ration, etc., could cause cholera. He replied in substance that the vitality of the animals might be weakened in this way, and thus make them more ready for disease, but that cholera could start only when the hogs came in contact with the germs that produce the disease, and when they were entirely removed from them the disease would end. There is no question about the advisability of taking good care of the hogs, and feeding them properly, as a preventive measure.

Dr. Ramsey, Assistant State Veterinarian, is also an earnest, sensible, practical young man. I am afraid much of his talk would not be relished by so-called "horse doctors." When telling farmers how to treat a horse that had the colic, for example, he said: "Go to some old lady and ask her what she would do for you if you had the colic, and treat your horse in the same way. Cover him up warmly, let him lie quietly, put cloths on the abdomen, wrung out of hot water, or put on mustard, and, perhaps, give some ginger tea." He said, in substance, that a horse with this disease is almost certain to get better soon. And when you dose him with all sorts of nauseous medicines, and take the horse out and ride him around, you are doing a cruel thing; and if the animal gets better, it is in spite of your treatment, not because of it. I suppose I enjoyed this talk more than some would, because I never did believe in dosing animals or human beings to any such extent as the common custom is. Our best doctors now give very little medicine, except to patients whose imagination it is necessary to work on, and then they often give bread pills, or some such harmless thing. In fact, there is one great doctor in the West who is performing the most wonderful cures without giving any medicine whatever. We have not a bottle of medicine in our home, and have never had the tenth part of the sickness that there was in my boyhood home, where dosing was about as common as eating.

THE DIVINING ROD, OR SWITCH, FOR FINDING WATER.

TELLING WHERE TO DIG WELLS, BY MEANS OF A WILLOW OR HAZEL SWITCH.

This is another humbug that needs to be thoroughly exposed; and such good papers as the *Country Gentleman* and *Practical Farmer* have published communications defending the institution, without any editorial or comment. Perhaps they proposed to let their correspondents discuss the matter. But I protest against letting such nonsense go unreprieved, even in a single issue. The writers of both the articles in question seem to be men of sense, and should know better. Look here, friends. There are but three imponderable agents known to science—heat, light, and electricity. One writer says it is no more strange than that the magnetic needles should point toward the north pole, about 3200 miles away. That may be true; but in the first place it is *not* the north pole that attracts the magnetic needle. And, again, the magnetic

needle will not point to a lump of ore away down in the ground. If it were true, and if the willow switch or hazel rod did point to veins of water many feet below, then we should have a new imponderable agent now unknown to science. Scientific men would rush to investigate, as they would hunt for a new planet or a new comet. It is a little strange that scientific investigation has paid so little attention to this matter. One experiment station took it up some years ago. Very likely it was our Ohio station. They showed up the fraud in very short meter by demanding that the water-witch should prophesy where water could be found, with his eyes *blindfolded*. The one called was an old gentleman who had located wells almost all his life. He was unquestionably honest and sincere in the matter, for he did the work for little or nothing. When the scientific experimenters, however, asked him if he could do it just as well blindfolded he replied that he could, without question; but when placed upon trial he entirely failed to set any stake where he had previously set them when he could use his eyes. The old man was honest enough to give up, and submit that he had probably not only deluded others, but had deluded himself all his life.

Now, you need not rush forward and try to "snow me under" with your testimonials or with your faith. If any of you have got a water-witch, north, south, east, or west, who can locate wells by the twisting of a switch, and who will locate them with his eyes blindfolded just as well as with his eyes open, just let me know about it, and I will make a trip expressly to see him, and pay you all for your time and trouble besides. Will the experiment stations of the different States help to get rid of this foolish, stupid legend of the Dark Ages? Make tests as I have outlined above, then send out bulletins, and have the matter published in the agricultural papers. Why, dear friends, just consider a moment. People have carried water long distances from wells all their lives because a water-witch drove a stake in that spot; and, again, one good friend of mine, I am told, has a well right square in front of his front door, because the water-witch told him he could not get water if he dug anywhere else. Perhaps a majority of the "witches" are honest. It simply illustrates how prone is humanity to get notions and to fall into ruts. Electropoise and patent medicines, spoken of in other pages in this issue, attest this. Why, it is just really enough to make a good man weep to see how people waste money and health by letting their imagination lead them astray. As a rule, men who put down wells by machinery, and do a large business, will tell you that the witching amounts to *nothing at all*. The man who put down our well where the big windmill now stands said he always drilled wherever people directed him to, and that a great many times they had a water-witch set the stake; but he said there was no question but the whole thing was a humbug, and, furthermore, that, when the matter was submitted to him, he always directed people to have their wells where it would be most convenient, and that the chances were certainly just as favorable for striking a heavy vein of water in one place as in another. They had never failed in getting plenty of water, providing they went *deep* enough. If somebody would dig for water where the witch says it can *not* be found, he would find plenty of it, with hardly an exception; for it is about as hard to dig far into the earth *without* finding a vein of water as it is to cut a finger without finding a vein of blood. That would prove the fallacy of at least half his claims, and with that would go the other half.

SANITARY DRAINAGE, ETC.

We are told in our book, "Tile Drainage," that the roots of trees never go into the tiles unless said tiles carry water when the ground generally is lacking in moisture. This condition would be secured only where the tiles carried water from springs, or slops and sewage from the house, cellar, etc. In digging up some tiles in Ernest's lawn we found the roots of different ornamental trees had got into the tiles, and spread out, making quite bushy roots. The reason was, these tiles carried drainage from the kitchen. Now, I have for some time been thinking we might take advantage of this fact. Water-closets are fast becoming desirable fixtures, and they are especially preferable to the dry-dust system where the internal water cure is to be used. Our books and periodicals on sanitary drainage, I believe, are recommending cesspools. Now, I do not want a cesspool anywhere on my premises. We put a water-closet, about a year ago, in our bath-room. A cast-iron pipe carries the sewage outside of the building; then vitrified sewer-pipe, with cemented joints, take it several rods down into the orchard. At this point the sewer-pipe is conducted into large-sized drain-tiles. We used first eight-inch tile, increasing to ten. As the ground slopes away from the house, there is no difficulty in getting a gradual fall, and at the same time keeping these large tiles within 20 or 24 inches of the surface of the ground through the orchard. By the way, these *large* drain tiles are some damaged ones that I got at the factory for a very small sum. They are cracked and warped from being overburned. These were just the thing, you see, to let the roots of the apple-trees, or any other kind of roots that take a notion, get through inside of the tiles. A good many shook their heads, and said it would not work. But how can it fail to work? The water used in flushing scatters the solid matter the whole length of these large tiles, and dissolves more or less of it every time it goes through. During our extreme drouth there was a dense growth of grass and clover over the large tiles, especially toward the lower end, but not the faintest smell could ever be perceived—of *course not*, for the growing plants took hold of it at once and converted it into something valuable.

We have just finished to-day, Dec. 22, putting a similar one for Ernest's home down through some rows of raspberries, currants, strawberries, pie-plant, etc. See cut on page 517, 1894. You see, the whole thing is automatic. The essentials are, to find a gentle slope in some direction away from the house; then the length of the line of tiles, as well as the size, will have to depend somewhat on the size of your family. Perhaps I should have added that the ground in our orchard and under the berry-plants is thoroughly tile-trained. These large tiles for sewage run right over the tile drains, the latter constantly disposing of the surplus water. There you have it—sewage taken away without any handling, and without ever seeing it; and you also have *sub-irrigation* and *liquid manure* combined. Of course, perfectly working sewer-traps are a necessity; and experts in the matter say there should also be a standpipe just beyond the trap, to carry any surplus gases up through the roof of your building. This prevents gases of any kind from forcing their way through the trap, as we are told they some-

times do during hot weather when fermentation is going on.

THE CRAIG SEEDLING POTATO.

I confess that my statement in regard to this potato has been received with more favor than I expected. A good many orders are made for pounds by mail, and quite a few for pecks, half-bushels, etc., by express, and some for barrels in the spring. Now permit me to make a suggestion. At the present value of this potato—\$5.00 a bushel—it can be grown under glass at a profit. I have raised potatoes under sashes more or less for several years back. They are one of the easiest plants to manage I ever had anything to do with, with this single exception—you must not let them freeze. But even if they do freeze, it does less damage than with any other plant I know of—that is, any other tender plant. If you scorch a tomato it is pretty apt to give up and die; but you may freeze the potato-tops clear down to the ground, and they will, as a rule, get right up and grow almost as well as if you had simply cut the tops off. Under glass, however, the ground seldom freezes. The principal damage is done to the tops. Well, I have had very good success in growing potatoes under glass. The only trouble is, they rarely sell for enough in our locality to pay. For instance, we rarely get more than 40 cts. a peck—sometimes 50; and if we raise a peck under each 3x6 ft. sash it gives us only 50 cts. for the use of the sash; whereas other crops give us from one to two dollars, and all the way up. Now, if you get a peck of potatoes under sash—and I think it can be easily done—this new Craig seedling is worth at present writing \$1.75 per peck, and this would pay very well. Furthermore, if you plant them now you could get potatoes ready to plant again in May or June. My impression is, however, that this new Craig potato will keep right on growing from now until next September or October; therefore you need not take the trouble to dig the potatoes and plant them again, but simply divide the hills. You can take a hill of potatoes and tear it to pieces, plant out the pieces like cabbage-plants, and even if some of the pieces have only a little root and top, they will grow just as readily as cabbage-plants.

If you have the ground very rich, and see that they do not lack for water, it is the easiest thing in the world to propagate potatoes from cuttings. T. B. Terry has told us what he got from a single barrel of potatoes (Freemans) when they were very valuable. Now I propose to tell you what I can do with a single barrel of Craigs by commencing some time in January. Of course, a greenhouse is much nicer than hot-beds or cold-frames; but the cold-frames will come in very nicely a little later in the season. If you have not got a greenhouse, nor any sash, you can work with a single pound by putting them into pots or boxes in the window. Manage just as you do with house-plants. Potatoes will grow pretty fairly, even if they do not have very much light. You have all seen them grow in dark cellars. Well, you can get them started with very little light, and keep on dividing, multiplying them until it is time to put them outdoors. The cotton-cloth beds, described in the tomato-book, will keep off a pretty severe freeze, say all in March and April.

Now, then, who among our readers will make the most pounds of Craig potatoes from a single pound between now and next October?

We clip the following from a recent number of the *Rural New-Yorker*, telling what Prof. Massey did a good many years ago:

In 1869, I propagated a whole greenhouse full of Early Rose in pots, and planted an acre of land from 35 pounds of seed which I had raised from a pound purchased from Mr. Bliss. The whole product was sold for seed, and I grew some of them myself. I have never had any Early Rose of late years equal to them. The plants I grew in pots, from cuttings under glass, made strong, vigorous plants, with a single stem, and rather exceeded in vigor any from cut potatoes being in four-inch pots of rich potting compost. All had set little tubers on top of the pots in the rank shade of the foliage, standing closely on the greenhouse benches. They were set out with unbroken balls of earth, and covered a little deeper. The tubers had a decided start, and grew at a more favorable season than if

they had been planted from sets outside. They were, in fact, mature before hot weather set in, and the seed potatoes raised from them in the fall kept solid, and made the finest of seed for the next season.

If I wanted to bring a new sort to the highest perfection for seed, I would propagate it in this way: get the tubers ripe in May, and then grow a good crop of seed from them in the fall. This seed would then give the type in perfection.

W. F. MASSEY.

A pound of the new potatoes to start with will cost you only 25 cts. See advertisement of friend Craig in another column. You can send the money to us or to him, as you choose.

CEMENT-COATED NAILS.

We are now using in almost all our work what are known as cement-coated nails. They are the ordinary wire nails with a thin coat of brown substance. The friction of the nail on the wood in driving softens this coating and makes it adhere to the wood while also adhering to the nail. This makes the nail hold better than any thing heretofore known. If you have ever tried to draw a rusty nail you know something how these nails hold. If you wish to investigate them we will mail a sample package of various sizes for 5 cents to pay postage.

We have been using these nails for several years, but have not offered them for sale before because we have not until recently been able to get most of the smaller and special nails used in our work with this coating. We have prevailed on the factory who control this coating process by patent, to coat our fine nails down to $\frac{1}{8}$ inch, and also casing nails used in nailing hives. The four smallest sizes in the following list will be smooth nails. We still have some stock of other sizes smooth which we will send while they last unless you specify cement-coated nails in your order. These cement nails hold so much better that a smaller nail can be used, and have greater holding power.

For instance, instead of $\frac{1}{4}$ -inch smooth nails we now use 2d fine or one-inch nails to nail up brood-frames and section-holders, and the work is stronger. On account of this greater holding power the patentees of the coating process adopted the plan of putting the same number of nails in a keg as the ordinary smooth nails will average, and make them a little scant in length and size so that a keg will be short in weight from 10 to 15 lbs., although having the same number of nails, and selling for the same price per keg. This plan made it difficult to fix a price by the pound, because kegs were not of uniform weight. Full-weight kegs of cement-coated nails cost more than the ordinary smooth nails.

PRICE LIST OF FINE FLAT-HEAD WIRE NAILS, CEMENT-COATED, EXCEPT FIRST FOUR.

8d "	$2\frac{1}{2}$ "	" 10 $\frac{1}{2}$	116	4	35	3 00
10d "	3 "	" 9 $\frac{1}{2}$	74	4	30	2 80
16d "	$3\frac{1}{2}$ "	" 8	46	4	30	2 70
20d "	4 "	" 6	29	4	30	2 60

The above table of prices is based on full-

weight kegs. Should we fill your order for full kegs with nails put up by count instead of by weight, the price of these by the keg will be about 10 per cent less. We have adopted for the coming season the plan of including with all goods sent out in the flat the right size and number of nails required to nail them, which we are sure will be a great convenience to our customers. We will, of course, use these cement-coated nails wherever we can. We are prepared with a stock of nearly a carload, and can get more as needed, though we have to order a month or two ahead of our needs to be sure to get them in time, because they are put up especially for us, and not generally offered for sale.

BINGHAM SMOKERS REDUCED.

The manufacturer announces reduced prices for this year in another column. We are, of course, prepared to supply you with his latest smokers at the new prices, and the new edition of the catalog will give the revised prices.

ROOT'S EXTRA POLISHED SECTIONS.

These are rapidly making their way into well-deserved favor among bee-keepers and dealers. We do not believe they are surpassed by any made anywhere, it is, indeed, they are equalled. We are almost daily in receipt of very flattering words concerning their excellent finish, color, and workmanship. We have booked a number of quite large orders, enough to keep us running steadily for about two months. We shall be pleased to hear from those dealers who have not yet made their arrangements for this year's supply. Samples mailed free to those interested.

OUR CATALOG FOR 1895.

From present outlook, our new catalog will hardly be ready to mail before the first of February. It is being entirely revised, re-arranged, and largely re-written, all of which takes time, when done in connection with our other work. It will not be necessary for our GLEANINGS subscribers to send a request for the new catalog, as a copy will be mailed to each as soon as ready, also to our list of customers and applicants, as fast as we can get them ready. If you can not wait for the new catalog, send us a list of the goods you want, and we will name our best prices.

A HIGH-GRADE BICYCLE CHEAP.

Desiring to ride the latest 1895 bicycle, I will sell my \$125 Victor Flyer, of '94 pattern, for \$75.00 in cash, or for \$80.00 worth of wax or first-class white honey, at market prices. This machine is practically as good as new, and on the rear wheel a new tire has been put. It has a full set of tools, extra inner tube for tires, rubber mud-guards. Weighs, stripped, or as I ride it, 29 lbs. Catalog giving full description will be sent if desired. To take advantage of this offer you will need to write quick, as this is a rare chance to convert your wax or honey into a bicycle. But don't send either till you write, giving particulars. E. R. ROOT.

COMB FOUNDATION.

We call attention again to the advance in list price announced in last number, made necessary by the advancing price of beeswax. This advance is adopted by all the leading manufacturers. Notice, also, we are paying a much better price for your wax, 26c. cash, 29 in trade, delivered here, for average, and extra for extra quality. In this connection we ask all of our readers not familiar with the excellent quality of our comb foundation, as now made, to send a request for free samples. Our output for 1894 was fully one-fourth more than for the year previous, and amounts to about 39 tons, notwithstanding the season was below the average generally.

SUGAR-MAKERS' SUPPLIES.

We call the attention of those of our readers interested in maple-sugar making, to our announcement in another column of sugar-makers' supplies, where we quote reduced prices all the way through the list.

TWO AND FIVE GALLON SQUARE CANS.

The reduction in the tariff on tin plate enables us to offer lower prices on square cans, one and five gallon, than we have made heretofore. We have also made arrangements to fill orders for these cans from New Orleans, as well as St. Louis, when more

convenient. You will find the reduced prices in the list of sugar-makers' supplies. Will quote large lots on application.

THE BUNCH SWEET POTATO, OR VINELESS YAM.

Mr. Wm. E. Price, of Eufaula, Ala., has 250 bushels of the above potatoes for sale. As he is in need of money to raise a mortgage, I am told he will sell them at a very low figure. These potatoes have been pretty thoroughly tested for a year or two back, and I believe they have generally given excellent satisfaction. They do well as far north as Michigan, and I understand good crops have been raised where the potatoes were not put out till July. In the South they plant them as late as August; but where put out so late, the potatoes are apt to be small, just as we want them for seed. For further particulars, address as above. A. I. ROOT.

COMFORT FOOT-STOVES.

We found, after we began advertising these this season, that the manufacturers are making much lower prices than last year, especially on the fuel. We therefore reduce our prices accordingly. The new prices are as follows:

Hand-stove, with 2 doz. fuel, 40c. each, \$3.50 per doz.

Small foot-stove, with 25 fuel, \$1.75 each; \$15.00 per doz.

Large foot-stove, with 25 fuel, \$2.00 each; \$16.50 per doz.

Fuel for hand-stove, 2c. for 2 doz.; \$1.00 per gross.

Fuel for foot-stove, \$1.00 per box of 50 sticks, \$9.00 per doz. boxes.

Hand-stove, with fuel, mailed for 10 cents extra.

We have had very flattering testimonials from some of those who bought stoves last winter and used them with great satisfaction and comfort. See advertisement or special circular for further particulars.

SPECIAL PREMIUMS.

Quite a number of our readers are abusing their privileges in regard to special-premium offers, no doubt through a misunderstanding of our offers. For instance, we offered, during last month, to send the *Farm Journal* free to every reader who renewed in advance, and claimed it. We have also offered the Gault raspberry (only one to each subscriber) at 25 cents to those who renew in advance, and we have offered a paper of March's cabbage seed to those who renew in advance. Then we offer a special clubbing price for GLEANINGS with other papers. Now, it is your option to take your choice from these special-premium offers; but it was not our intention that the same person could take advantage of all of them on the same subscription, as some seem to have the idea they can do. When we offer a special premium for renewal in advance, it means that you must pay the full subscription price of \$1.00 before the expiration of the old subscription, or before the new begins, to secure that premium; and if we offer several such special premiums you can take advantage of but one, on the same subscription, and your request for special premium must be made at the same time, not some time afterward. From now on, for this month, those who would have the *Farm Journal* with GLEANINGS must pay \$1.10 for the two, and then it must be a paid-in-advance subscription. If you are in arrears, all arrears must be paid, and \$1.10 sent in addition for the year in advance, for both papers. The paper of March's cabbage seed may be claimed in addition to any other one special premium, or in connection with GLEANINGS, clubbed with other papers. The *Farm Journal* may be added to any of the clubbing offers for 20 cents extra, or to any of the special-premium offers for same amount.

MAPLE-SUGAR SUPPLIES.

The time is at hand when those who produce the delicious sweets from the sugar maple must be getting ready. For the best results you must have good clean apparatus of the most approved type, and you really can not afford not to read Prof. Cook's book, "Maple Sugar and the Sugar-bush," which we furnish at 35c, or we will give a copy free to all those who buy sugar-makers' supplies of us to the amount of \$10.00 or more. We do not sell evaporators, but we think we can do you some good on spouts, pails, covers, and cans. We have received a carload of these from the factory, and they are made of American tin-plate. The plates are tinned

Largest Factory in the West. **COMPLETE STOCK.**

B 4 U Buy Seeds or Plants,

Send for my Annual Catalog.

It is neatly gotten up; no old stereotyped matter about it; nothing sensational. The Best Varieties **truthfully described and honestly priced.** A. I. Root says, "I believe I have read every catalog you have put out clear through, and I wish all seedsmen would tell us their experience with different varieties as frankly as you do." True Prizetaker onion seed and plants a specialty. Vegetable and small-fruit plants of all kinds, trees, and supplies for gardeners. Send for free catalog at once, or send 10c for catalog, a pkt. of a new smooth very early tomato, a pkt. of the best new lettuce, a pkt. of true Prizetaker onion, and a pkt. of choice flower seeds, all for 10 cents.

Christian Weckesser, Niagara Falls, N. Y.

HONEY COLUMN

CITY MARKETS.

KANSAS CITY.—*Honey.*—The stock of comb honey is large; market well supplied. Fancy white 1-lb. combs, 15; amber, 12@13. Receipts of extracted, light; white, 7; amber, 5½@6; southern, 4½@5. Beeswax, 22.
HAMLIN & BEARSS,
 Jan. 7. Kansas City, Mo.

CINCINNATI.—*Honey.*—Demand is very quiet since the holidays, and prices are the same. Comb honey brings 14@16 for best white, and extracted 4@7 on arrival. There is a good demand for beeswax at 23@28 for good to choice yellow.
CHAS. F. MUTH & SON,
 Jan. 7. Cincinnati, O.

DETROIT.—*Honey.*—Sales some slower since holidays. Stock not large. Best white comb, 14@15; dark lots, 10@13; extracted, 6½@7. Beeswax, 26@27.
M. H. HUNT,
 Jan. 7. Bell Branch, Mich.

BUFFALO.—*Honey.*—In the honey market there is very little doing. Fancy is moving off in a moderate way at 13@14; choice, 11@12; buckwheat, 8@9. Extracted dull; we would not advise shipments of any honey at present.
BATTERSON & CO.,
 Jan. 7. Buffalo, N. Y.

KANSAS CITY.—*Honey.*—The demand for both comb and extracted is light; supply good. We quote No. 1 white comb, 14@15; No. 2, 12@13; No. 1 amber, 13; No. 2, 10@11. Extracted, white, 6@6½; amber, 5@5½; dark, 4½. Beeswax, 22@25.
C. C. CLEMONS & CO.,
 Jan. 7. Kansas City, Mo.

ALBANY.—*Honey.* The honey market is very quiet, as is generally the case during the first of the year. The demand for extracted usually commences about the middle of January. The stock of comb honey on hand is not large, especially clover; but the supply of extracted is ample. We quote clover, 12@13; buckwheat and mixed, 9@10. Extracted, 5@7.
CHAS. McCULLOCH & CO.,
 Jan. 8. Albany, N. Y.

CLEVELAND. *Honey.* Our honey market has not been as firm as anticipated, and it has not been in very great demand for the past few days. No. 1 white is selling at 14@15; No. 2, 11@12. No. 1 white extracted, 6. Beeswax is in good demand at 26.
WILLIAMS BROS.,
 Jan. 5. 80 & 82 Broadway, Cleveland, O.

ST. LOUIS.—*Honey.*—The trade is quiet on all grades of comb and extracted. We quote clover comb, 16; amber, 12½@14; extracted in cans, 5½@6; in barrels, 4@4½. Prime beeswax, 28.
D. G. TUTT GROCER CO.,
 Jan. 7. St. Louis, Mo.

NEW YORK.—*Honey.*—The demand for comb honey has been very light of late, and has now almost dwindled down to nothing. The supply has been larger than any year before, and there is a large stock on the market. In order to move it in round lots, it will be necessary to make concessions from the ruling quotations. Buckwheat and off grades are almost unsalable. We quote: Fancy white 1-lbs., 12@13; off grades, 10@11; buckwheat, 9. The demand for extracted continues very light, with plenty of stock on the market and arriving. We quote: White clover and basswood, 6; buckwheat, 5@5½; southern, per gal., 50@55. Beeswax is in good demand, and finds ready sale on arrival at 30@31.
HILDBRETH BROS. & SEGELKEN,
 Jan. 9. 28 & 30 Broadway, New York.

BOSTON. *Honey.* Our honey market remains about as it has been, with light demand. Comb honey, 14c; extracted, 5@6c.
E. E. BLAKE & CO.,
 Jan. 10. Boston, Mass.

CHICAGO.—*Honey.*—Honey is selling but slowly at this season, but we expect an increase in demand within the next fortnight. Choice white sells at 14c; dark grades, 9@12. White extracted, 6@7; dark, 5@6. Beeswax, 27c.
R. A. BURNETT & CO.,
 Jan. 12. 183 So. Water St., Chicago, Ill.

SAN FRANCISCO.—*Honey.*—White extracted honey, 6@6½c; light amber honey, 5@5½; 1-lb. frame comb honey, white, 11c. Beeswax is scarce at 26@27c.
SCHACHT, LEMCKE & STEINER,
 Jan. 10. San Francisco, Cal.

DENVER.—*Honey.*—Our market seems to remain the same. We quote No. 1 white comb honey in 1-lb. sections, put up in 24-lb. cases, suitable for putting in cartons, 11@12 cts.; No. 2, in cases, 10. No. 1 extracted, in 60-lb. cans, 6@7c. Demand for extracted honey is quiet, with a good supply on the market. Beeswax, 22@25 per lb. We could handle to advantage a quantity of 1-lb. comb honey.
R. K. & J. C. FRISBEE,
 Jan. 9. Denver, Col.

Closing out balance of my fine extracted basswood honey at 7c f. o. b. Who is not supplied?
ELIAS FOX, Hillsboro, Wis.

FOR SALE.—Honey, in 60-lb. cans, 6c; 52-gal. barrels, at 5c. Send for sample.
W. C. GATHRIGHT, Cameron, Tex.

We yet have extracted alfalfa at \$7.80 per box of 120 lbs.
AIKIN BROS., Loveland, Colo.

FOR SALE.—4 bbls. of No. 1 extracted basswood honey. Weight, 562, 552, 336, and 275 lbs. net, at 6½c per lb. f. o. b. here.
E. D. TOWNSEND,
 Carson City, Mich.

ALFALFA HONEY, very white, thick, and rich. Two 60-lb. cans at 7c. Same, partly from cleome (tinted), 6c. Samples, 8c.
OLIVER FOSTER, Las Animas, Col.

Having secured a fine quantity of buckwheat extracted honey I now offer it in lots to suit purchaser, 210-lb. kegs at 5½c, f. o. b.; also 2000 lbs. of basswood and clover.
W. LAMAR COGGSHALL,
 eitf West Groton, Tompkins Co., N. Y.

HONEY FOR SALE.

I have about 3000 lbs. A No. 1 fall honey, three distinct flavors—Spanish needle (smirtnweed or hearts-ease), and aster, 7c per lb., f. o. b. Sample free.

Wants or Exchange Department.

Notices will be inserted under this head at one-half our usual rates. All advertisements intended for this department must not exceed five lines, and you must say you want your ad in this department, or we will not be responsible for errors. You can have the notice as many lines as you please, but all over five lines will cost you according to our regular rates. This department is intended only for bona fide exchanges. Exchanges for cash or for price lists, or notices offering articles for sale, can not be inserted under this head. For such our regular rates of 20 cts. a line will be charged, and they will be put with the regular advertisements. We can not be responsible for dissatisfaction arising from these "swaps."

WANTED.—To exchange a 200-egg improved Excelsior incubator complete, in A 1 condition, costing \$25.00, for best offer of 1½-story Dove-tailed hives complete for comb honey, or other bee-keepers' supplies. **FRANK LACEY, Danbury, Conn.**

WANTED.—Two or three hundred colonies of bees to run on shares for comb or extracted honey the coming season, or to take charge of as apiarist. Reference, **W. L. Coggeshall, West Groton, N. Y.** **RUSSELL T. STINNETT, Bells, Va.**

WANTED.—To exchange for any thing useful fox-hound pups, Bull terriers, butchers' tools, bone-mill, and White Holland turkey gobbler. Write at once, as this will not appear again. **ELIAS FOX, Hillsboro, Wis.**

WANTED.—To exchange one-piece-section machine, steel feed-grinder (½ ton per hour), 8 H. P. engine, 25 ft. 8-inch rubber belt, for brood fdn. or Hoffman frames with comb wired. **A. D. D. WOOD, Lansing, Mich.**

WANTED.—To exchange a good heavy 24-in. planer, a good cut-off saw-table a queen-age boring-machine, a Novice honey-extractor (new), a Pelham foundation-mill, and a lot of supplies. What have you to trade? **A. A. WEAVER, Warrensburg, Mo.**

WANTED.—To exchange rabbit-hound pups (English Beagle) for Winchester rifle or offers. Choice stock and low prices. **D. S. HALL, So. Cabot, Vt.**

WANTED.—A good Winchester or a Colt's repeating-rifle, from 32 to 38 caliber, for which I will exchange first-class sections, foundation, or bushel boxes. Circular and price list free, and free samples of sections or foundation if called for. Address **O. H. TOWNSEND, Alamo, Kalamazoo Co., Mich.**

WANTED.—To exchange Cuthbert or Marlborough raspberry-plants for beeswax, honey, or offers. **C. G. MARSH, Belden, N. Y.**

WANTED.—To exchange 1 span of large mules; also wagon, harness, and mares, for 200 colonies of bees. **BERT W. HOPPER, Garden City, Kas.**

WANTED.—Position in an apiary, by a young man of experience. Florida preferred. Write to me at once. Who will give me a chance? **MARION H. GILMER, 607 Louisiana St., Station B, Richmond, Va.**

WANTED.—By young man, position in large apiary. Do not use tobacco or liquor; 8 years on a garden, 3 on a dairy farm; accustomed to bees. **CARE BOX 382, Hamburg, Erie Co., N. Y.**

WANTED.—Offers on a new 20-egg Noxall incubator at \$15. **R. C. AIKIN, Loveland, Colo.**

WANTED.—To exchange supplies and other goods for honey. **O. H. HYATT, Shenandoah, Iowa, 20tf**

WANTED.—To exchange several good safety bicycles. Honey wanted. Send sample. **J. A. GREEN, Ottawa, Ill.**

WANTED.—To exchange 200 colonies of bees for any thing useful on plantation. **ANTHONY OPP, Helena, Ark.**

WANTED.—To exchange pure St. Bernard pups, from registered stock. Will exchange for any thing useful. Would like a portrait-lens. Address with stamp. **SCOTT BRILLHART, Millwood, Knox Co., O.**

WANTED.—For spring planting, apple, quince, currants, gooseberry, strawberry, in exchange for golden queens, in June. **J. F. MICHAEL, Greenville, O.**

WANTED.—To exchange a Simplex 160-egg incubator and brooder combined, used 2 settings, for 150 lbs. of light or 175 lbs. of buckwheat extracted honey, in tin cans. **J. T. VAN PETTEN, Linn, Kansas.**

Florida and ALL Southern Bee-keepers,

Do you know that the freight rates (by water) are one half less from *here*, than from any place you can obtain a full line of supplies.

Rate on bee-hive material, to

Jacksonville, Fla., 18c per 100.

Men Who Make the Review.

M. M. BALDRIDGE,
ST. CHARLES, ILL.

B. TAYLOR,
FORESTVILLE, MINN.

THE success and usefulness of a periodical are largely dependent upon the men chosen by the editor as correspondents, hence it is worth while to notice who are the *Review* correspondents, and how they were secured.

During the past seventeen years the editor of the *Review* has attended nearly every bee-keepers' convention of a national character; has visited scores and scores of bee-keepers in their own homes, and received and answered thousands upon thousands of letters; in short, he has enjoyed, and still enjoys, a personal acquaintance with most of the leading bee-keepers of the country. When he wishes for information upon some special topic he knows *exactly* where to find it. He knows who is posted on this point, who on that—who rides this hobby, who that; and this wide acquaintance has enabled him to choose, as his principal correspondents, successful, practical men, most of whom have numbered their colonies by the hundred and sent honey to market by the ton, and who can write, from experience, articles containing information of real benefit to honey-producers.

The *Bee-keepers' Review* is \$1.00 a year, or \$1.25 for the *Review* and the book "Advanced Bee Culture."

My new Catalogue of

Small Fruits, Free

To every reader of this journal. All leading old and new varieties. *Largest stock in Ohio. Lowest prices.* Many new novelties, such as Greenville and Timbrell strawberries, Eureka and Miller raspberries, Eldorado and Ohmer blackberries, North Star currants, Crosby peach, etc., etc. Catalogue free.

New Curlists, O. W. N. Scarff.

Attention, Bee-keepers!

Remember Jennie Atchley will mail you untested queens any day in the year for \$1.00. She is now preparing to fill your orders for queens and bees in 1895.

January to June prices. Untested, \$1.00, 6 for \$5.00, \$9.00 per doz. Tested, 3-banded, \$1.50; 5-banded, \$2.50. Tested Carniolans, \$2.50. I will rear the leather-colored Ital's, or 3-banded; silver-gray Carniolans, and 5-banded, in separate yards at safe distance. Bees by the pound, \$1.00. Nuclei, per frame, \$1.00. This is one of my specialties.

Write me for prices on large lots and to the trade. Catalog ready Jan. 1.

I have been at this business long enough to know how to ship, and please customers. All Bee Supplies. Dovetailed Hives, Root's Goods, and Dadant's Foundation. Figure out what you want, and write for estimate.

Jennie Atchley,

Bee Co.

No. 2.

STRAY STRAWS

FROM DR. C. C. MILLER.

311 MEMBERS in the Bee-keepers' Union.

POPPLETON's pineapples, page 15, are peculiarly tantalizing to those of us who can't afford the luxury.

SPHAGNUM, or nurserymen's moss, is highly commended in *Le Progres Apicole* for absorbent material.

ERNEST's visit to the Frances reminds me that, years ago, I visited the place but hadn't the courage to introduce myself.

THOSE WHO INJURE larvæ, as mentioned p. 21, by using a quill toothpick, would do well to try a joint of grass cut toothpick fashion.

I CAN WAIT till February for the new catalog; but when's the seed catalog coming? A horticulturally crazy brother-in-law has been asking me.

C. W. LEARNED, in *A. B. J.*, says a five-banded queen carries more safely in the mail than a common one—"the more hoops, or bands, the less danger of bursting up!"

STRAW-COLORED sugar (*sucre candi jaune-paille*) is recommended in *L'Apiculteur* for feeding bees. No water; just put the dry crystals over the frames and cover up.

EXPERIMENTER TAYLOR fed back to get sections filled, feeding 1.61 lbs. extracted honey to get 1 lb. stored. That is, he had filled in sections more than $\frac{3}{4}$ as much as he fed.

COMPLAINT is made in *Le Progres Apicole* of a law that imposes a fine of \$1 to \$3 upon any one who places bees less than 4 rods from a dwelling or a public highway. No wonder!

CAPITAL IDEA that, of sending the right kind and amount of nails with goods in flat. I never can tell for sure the right nails for a new thing, and sometimes I can't get them.

BEE-KEEPERS at the Rockford convention, who, perhaps, had no better pasturage than I, got more honey. Perhaps the reason was their

smaller number of colonies. If I had had only one-tenth as many bees, I feel confident I should have had ten times as much surplus.

A DANGEROUS RIVAL to A. I. Root has turned up in no less a person than our quaint friend B. Taylor, who proposes to get his living out of an acre of ground, just for the fun of it. See *Review*.

QUITE AN ARRAY of exposes on pages 26 to 29. Keep at it, friend Root—makes good reading; and although some people are never happy without being humbugged, the hard-earned dollars of others may be saved.

R. MCKNIGHT, in his *St. Joe* paper, says the Ontario Bee-keepers' Association "is the best and solidest organization of its kind on this continent." The worst of it is, that what he says is true. Yankees can't come up to Kanucks in that sort of thing.

FRIEND ROOT, sorry to see you, on p. 26, give currency to that hoary error that "the forest leaves are decorated by the first frosts of autumn." We often have beautiful autumn foliage before frost, and the tendency of the frost is to stop the coloring.

SAY, BARNEY, what's the row in the printing-office? Four mistakes in three consecutive lines on p. 27. Form not locked tight enough, eh? [Type will sometimes pull out in spite of anything we can do. It was all right when it went down to the press.—Ed.]

THE VERY INTELLIGENT set of York State bee-keepers of the present day are not likely to be succeeded by a set of ignoramuses. The new law requires that every child between 6 and 14 years of age shall attend continuously during the school year some recognized institution.

"THE OLD RELIABLE" celebrates the new year by putting on a new dress, and shedding with the old dress the editorial "we." It also prints its own name the same as any proper name. There's an example for you to follow, Mr. GLEANINGS. [That's a matter of taste, Mr. Doctor.—Ed.]

CARBONYLE, used to paint hives, according to J. Chardin in *Le Rucher*, makes them last sev-

eral times the ordinary length of time, and costs only 3c a hive. But who will tell us what is carbonyl? Perhaps some hideously smelling preparation of coal oil, for it must be dried six weeks before bees will stand it.

G. W. HOLE, in *B. B. J.*, says, "With regard to clipping of queens' wings, there are hundreds of otherwise good bee-keepers who can not pick her out from among her sisters, even if willing to mutilate her." Seems a bit queer to speak of a good bee-keeper who can't tell a queen from a worker.

THAT 19 TONS OF foundation you made in 1894 was a lot. Let's figure. Made 6 ft. to the pound, it would cover more than 5 acres, and fill 256,750 L. frames. Made 10 to the pound, and $3\frac{3}{4}$ in. wide, it would make a strip 230 miles long, and fill sections for 1945 tons honey. [Thanks. Figures are not always intelligible except by comparison.—ED.]

B. TAYLOR, in *Review*, mentions a bee-keeper whom a bee-journal held up approvingly, saying that he "wasted no time fooling with experiments, but just adopted the Quinby hive and system, and went right along making big crops of honey." Then Mr. Taylor shrewdly asks, "But suppose Mr. Quinby had been like this excellent man."

SWEET CLOVER seems to be feared with an insane fear, as a bad weed. Perhaps this comes from the fact that it will hold its own where nothing else will grow. But will it run out a field of red clover or timothy? A few years ago I had a piece occupied with sweet and red clover. First the red came up and hid the sweet, then the sweet shot up in June and hid the red. But since that year the red has gained the ground.

CEMENT-COATED NAILS must be a good thing; but please tell us whether they are any better than rusted nails. [Rusty nails are good, but they don't hold like the new cement-coated, for I've just been trying the experiment. Had a hard time to find some rusty nails around our establishment. The cement is always uniform, while the rusty chaps are apt to be pitted or rusted too much for their real strength. Say, are your nails rusty from choice or because they happen to be so?—ED.]

A FLORIDA PAPER has an appeal for bee-keepers to contribute a pound of honey for each hive to father Langstroth, on the ground that his hive was never patented. That's a mistake. The hive was patented, but it was pirated in such a way that he never got the profit to which he was fairly entitled, and it would be a graceful thing for bee-keepers to contribute to the fund being raised by the editor of the *American Bee Journal*. [That's a move in the right direction; but how are the pounds of honey to be collected together without a large expense? A better way is to send the *value* of one section for every hive to the editor of the

American Bee Journal. The money can be conveyed with no danger of breakage or leakage, and for only two or three cents.—ED.]

SEALED COVERS.

ARRANGEMENT OF OUT-YARDS, ETC.

By E. France.

Who says sealed covers are no good? Others are afraid of them, I suppose, because they have never tried them. We cover all our bees with a solid board, made out of inch lumber, dressed on both sides, cleated at the ends to keep from warping. Over this board we put into the chamber some straw four to six inches deep. The top chamber is made deep enough to hold that much. On some of our hives we have cushions to lay on top of the honey-board—cushions filled with chaff six inches deep. I like the straw just as well. The farmers where we keep the bees furnish the straw. About May 1st to the middle of the month we take the straw out and throw it in piles out of the way. If we use the cushions they are in the way all summer, as we have no place to store them away. We have been using those sealed covers—honey-boards we call them—over 30 years, and have always wintered outdoors on the summer stands. I think we have averaged as good luck as most bee-keepers. Our winter losses are usually light.

I have tried covering bees with cloth cushions, stuffed with chaff, straw, and leaves. I find no better way than putting the solid honey-board right on next to the bees, and covering with straw. We prefer to winter out of doors. I have tried cellar wintering, and did not do as well as out of doors. Now, this brings me to another subject—

HIVES FOR OUTDOOR WINTERING.

I want a quadruple hive, four colonies in one hive, and I want a large hive at that. Then we never have any little weak colonies—all are good and strong. Make all increase by division, and always make a new colony—a full colony, especially if made late in the season.

FRAMES, EIGHT OR TEN.

I have been very much interested in the discussion of the question as to eight or ten frames. I don't know but that I am on the fence, with Dr. Miller. I have eight-frame hives enough to hold over 150 colonies; but if you ask me if eight frames are my choice, I don't really know. I have been led to use them, whether it was my choice or not, in this way: I first made one hive to hold four colonies on L. frames. I made it to use nine frames in each set—two stories high. After I had it finished I found it was too wide-

to slip into a common wagon-box; and as I expected to haul them sometimes from place to place I changed; and all that I made after the first I made to use eight frames in a set, so that is the way it happened that I am using eight frames. I soon discovered that two sets of eight frames did not give me comb room enough; so then, to have more comb room, I put on the third story. In the honey-gathering season I use 24 combs. I think it is none too many. I am still using my nine-frame hive with a third story added—27 frames—and I don't think that is too large. I have 140 colonies in my home yard, and have combs enough to fill all three stories high. For winter I take off the third stories and pack them away in my comb-room. I make sure that the second story is full of honey. I want at least a part of the lower combs to be empty when cold freezing weather sets in; then the bees will cluster in the empty combs just below the honey, and will work up as they eat the feed, no matter how cold the weather is. I think there is at least 2000 lbs. of honey now in my comb-room, that I took off with those third stories, so the bees are in no danger of starving, as they had their second story full in the fall.

In the spring, in March or April, I look the bees over. If any are getting short of honey I change their empty combs for full ones taken from the honey-room. In the spring we work to get all colonies strong; and as soon as the two lower stories are full of bees we put on the third stories and fill up with the combs from the store-room—honey and all. We usually get that on two or three weeks before we commence to extract. By that time the combs will extract nicely.

Mr. Hatch seems to think, in GLEANINGS for July 15, that, if a queen keeps eight frames full of brood, they are boomers. If I had a queen that did not equal eight frames of brood during the breeding-season, she is no queen for me. With our L. frames we keep the lower story of eight frames full of brood, and the surplus brood-combs we make into new colonies. In that way I made 45 new colonies this year, 1894, from 95 old ones, and every one of the new ones were given eight good brood-combs—360 brood-combs, or on an average of nearly four combs from each queen, to keep the brood down to eight combs; no natural swarming to speak of. We very seldom have a natural swarm. We don't have them to hive. When we are extracting we take all the honey we can get from the two upper stories, and keep the brood below. If I should find a brood-comb in the second story, and an empty one in the lower, I would put the empty one up and the brood below. Eight combs, kept at work breeding bees for a three-story hive, will keep bees enough in the hive to fill the two upper ones with honey, in a good flow, once in a week; so they can be emptied once a week; and bees with me worked

in that way don't swarm. I don't know but a three-story ten-frame would give more honey to the hive than the eight-frame. There would be larger colonies, but you could not get as much increase, as it would require ten brood-combs in the lower tier to breed enough bees to work the upper twenty honey-combs. This brings me to another point—

LIFTING HIVES AND TOP STORIES FULL OF HONEY.

I don't have to lift hives. No man can lift my quadruple hives when full. Three stories will weigh at least 400 lbs., and I think more. I am getting too old and feeble to lift a top story full of honey. I use a hand-cart at home, where my L. hives are. For a few years past I have run that yard myself, with the help of one and sometimes two hired boys. My cart will hold four carrying-boxes. The boxes are made with bottoms, two sides, and back boards. The front is left off. They will hold ten combs each, if full. The combs hang on top of the end boards; cleats are nailed on the outside of the end boards to handle them by. When extracting I fill two boxes with empty combs; put them on the cart, then either myself or boy runs the cart alongside of one of my big hives, then turns one half of the top chamber over on to the other half. Now we can work two colonies—pry up the honey-board of one, smoke the bees down and brush off what few bees there may be on them; hang the combs in the empty boxes on the cart; when the third story is empty, lift it off and set it down on the ground, then smoke and take out the second story; set and hang them in the other empty box. Now fill up the hives with your empty combs; put on the honey-board, wheel the cart to the extracting-house, slide the full boxes off on to a platform on a level with the cart. You will not need to lift it. When they are extracted, take them back to fill out the next one worked. Why not use a bee-escape to get the bees out of those combs? Too much lifting to put them on, and I don't think the bees can be got out of the second or middle story any way, with an escape, as there is very likely to be some brood in it. It doesn't matter, however, as I can take the combs out of the two upper stories in five minutes, and no lifting except taking the combs out one at a time.

Now, Ernest, if you can not get along with your out-apiaries run for extracting without so much lifting, come here and let me give you a few lessons. But let me tell you, if you run a good-sized yard for extracted honey you will want some help during the extracting season.

This brings me to another point. When you travel over the country I think sometimes you go too fast. You would do better to take more time. When you got to Platteville you put up at the hotel, and came to our place after church time, Sunday. I told you then that you deserved a whipping for not coming out the night be-

fore. Well, it was Sunday, and I did not feel at liberty to talk bees to you. I expected you would stay over on Monday. My wife took you off to church Sunday evening, and Newell took you to the powder-mills Sunday afternoon, and the train left at 9 A. M., and away you went, so I had but very little time to talk with you. There were very many things I wanted to talk about, and some things I wanted to show you. I expected to take you out to some of our out-yards. We could make three yards in half a day, and talk over bee matters on the road. It costs considerably to get to a place; and when you are there, why not stay long enough to do some good?

Platteville, Wis., Dec. 17.

[Yes, I am afraid we condemned the sealed covers too hastily; and without saying any thing about it in print, I decided we would give the matter another test this winter, though perhaps not on quite so large a scale as before. One half of our colonies at the out-yard are under sealed covers, and the other half under absorbing cushions.]

I know I appeared to be in a hurry while I was at your place; but the fact is, I hurried at all the places—one reason for this being that I had a good many calls to make, and limited time; and another reason was, I feared in some cases I might be a "bore;" but since I have come away and read your last two articles I see that I missed it in not *taking* more time. But after all, our general readers would not have gotten the information regarding the methods of management so fully and accurately as from your pen; but at all events, next time I come I will go straight to the France home and stay till you get tired of me; so, look out.—Ed.]

LARGE VS. SMALL HIVES.

REASONS WHY THE TEN FRAME IS BETTER
THAN THE EIGHT.

By S. C. Cowin.

Friend Root:—I conclude, by reading Mr. Gill's article, which you indorse, that he runs his apiary for extracted honey. It may sound strange, but my experience is that an eight-frame hive is better for extracted than for comb honey, and for this locality it is not good for either kind. I should like to know whether Mr. Gill ever tried his eight-frame hives four stories. I have; and to lift that fourth story is much harder than lifting a third ten-frame story, because it is a lift at arms' length. My hives are on stands eight inches, and it puts a fourth story above good lifting position. Mr. Gill also says, and it's my experience, that, after filling six or seven frames, they *prefer* to occupy two frames above; and if allowed, they will do so; and, as I said in my former article, it gives us ten or eleven frames of brood, and we are obliged to go into the brood-chamber to get this honey which is in the other five or six frames, or leave it through the season, cutting our brood-nest to the size of a ten-frame hive, or any mat near it. This is about the way eight and ten

frame hives have worked for me this past season. The ten-frame brood-chamber gave me about nine frames of brood, with two extracting-supers, each having nine frames working the same as for comb honey, raising the partly filled one and placing the empty combs between the upper and lower stories. This gave me strong colonies with plenty of room, and very little swarming. The eight-frame hives were run two stories for brood-chamber, and gave from ten to eleven, and in a few cases as many as twelve, frames of brood. Two stories were run for surplus, each having seven frames, giving fourteen frames, or four frames less than the ten-frame hive; and as they had more brood they gave rousing big colonies, but also gave me more swarms. Had I gone below and extracted, the result might have been different; but I do not go into the brood-nest after the surplus season opens. Again, I use the large size Daisy wheelbarrow for running my combs to the extracting-room. It takes two ten-frame bodies crosswise and one lengthwise on top of the two, and hard against the head of the barrow, putting most of the load near the wheel, carrying 27 combs at a load. With the eight-frame body I can carry only the same number of bodies holding 21 extracting-combs, or a difference of six combs, or more than 35 pounds of honey at each load less with eight-frame than with ten-frame bodies. You will say, carry four eight-frame bodies crosswise. The slant of the wheelbarrow head lets the square-edge body slide forward and push up the frames; and a bevel edge, not having any thing to hold it, is apt to tip over, and then the two stories so near the hands makes too much of a load.

Mr. Gill wants us to do without dummies and one-story in harvest while he *tiers up* to show us the superiority of the eight-frame hive. Let us take the eight and ten frame, use them to the best of our ability to secure large crops, and I think you will find the ten-frame hive ahead. This has been my experience, and my order this fall calls for ten-frame Dovetailed hives.

Sarasota, Fla., Nov. 23.

[As I read over your article I could not help seeing the point you make; but somehow the thought kept coming into my mind, Would not the 12-frame be better than the ten-frame? That is, the same arguments apply very largely in the case of the 12 over the 10 as in the case of the 10 over the 8. But the 12 is away off from the standard. The thought came to me again. Is not the 16-frame hive better than the 12 frame? if so, then the two 8's, rather than one large 16, should have the preference, so that we can adapt the colony to the season and to the locality. Regarding this, in the last *American Apiculturist* Mr. Henry Alley gets in a good deal of truth something after this fashion:—

[Ed.]

How will the big bee-men settle the question as to whether an eight-frame or a ten-frame hive gives the better result? In GLEANINGS for November 15, two experienced bee-keepers give their experience with hives having eight and ten frames. One of the

above parties says the eight-frame hives gave the best results, while the other man says his colonies in the ten-frame hives did the best.

This is exactly as it always will be. In some cases ten frames will be found best, while in other cases the eight-frame hive will do equally well, if not better. The question of the right number of frames to use must be decided by each bee-keeper for himself.

SHORT VS. LONG LANGSTROTH FRAMES.

WHY THE FORMER ARE PREFERRED: THE DISCUSSION OF LONG AND SHORT FRAMES, AND OF THE LANGSTROTH IN PARTICULAR.

By John Craycraft.

The discussion for and against the eight-frame hive has been read carefully, and I should be pleased to give my experience.

About 15 years ago I used the ten-frame Langstroth hive in Indiana. I then became convinced that it was not the best for economy. I changed part of my frames so as to hang crosswise in the ten-frame hive—that is, I made the frame $9\frac{1}{2} \times 13\frac{3}{8}$ inches—what is commonly called now the short Langstroth frame. I then found I could winter bees better on the short frame, for the simple reason that the bees could form themselves into a more compact body than they possibly could on the long frames during the long cold winter. Then, again, in the spring, when breeding commenced, they could and did breed up with more rapidity than I could possibly get hives with the long frames which were sitting beside the ones with the short frames. This all came from the more square and compact form the bees could form themselves into, which was not possible for them to do on the long frames early in the season, when ordinarily there are not more than enough bees to cover five Langstroth frames.

This is where I found that there was economy in the short frame and a smaller hive, and for spring increase. It is a self-evident fact, that a more uniform temperature can be maintained by the same quantity of bees on ten short frames in a square hive than the same bees can on eight long frames whose space is about the same in comb and cubic contents. I kept this test there for three years, and then I sold out and came to Florida in the fall of 1883. I then started with a few colonies all on the short frames, with square hives, $14\frac{1}{4} \times 14\frac{1}{4}$ in., same depth as the regular Langstroth hive and frame, keeping about 20 colonies until this season, when I increased my stock up to 110 colonies, all on short frames, 10 of them in the brood-chamber, which is made with a tight bottom. All have tin roofs raised two inches above the frames. In the spring I start them up seven weeks before the usual time of orange-bloom, so that, by that time, I have the brood-chamber full, and usually one story above full of brood in various stages. I give queens full play to the top as long as I want

honey-gatherers reared; then I shut the queen below to the brood-chamber with zinc excluders, and add more stories, if needed, by raising the ones up and placing an empty story next to the brood-chamber, filled with comb foundation usually, but I have found that starters are about as good, except there is some more danger of drone comb being built. By thus tiering up, and letting all honey be sealed up, I can get good honey, well ripened in the hive, and keep my bees busy all the time, by thus keeping space vacant near the brood and queen.

I see there are some doubts and failures about getting queens to go up into the story above. I have very little trouble; for when a brood-chamber is becoming crowded I remove two frames of sealed hatching brood from below, placing combs in their place below, putting these two frames of brood in the center, and filling in combs on each side. I then scarcely ever fail to get the queen up there, and I have had them up in the fourth story the past season.

Thus by proper management with the small square hive with the short frame, I have a small compact hive when most needed, and a large one when most needed also, besides using the surplus heat to ripen and cure my honey on the hive, with no loss of bee labor.

With this square hive and short frame I have all the advantages for comb honey that can be obtained in any long-frame hive; with half-stories I can work them with and on the same hive for both comb and extracted. If I wish to work a hive for comb I raise up the story above the brood and place a half-story next to brood, placing the full-story on it. I let the half-story of sections remain below until nearly ready to commence sealing them. I remove to the top or remove the story above, and place another half-story under the one being sealed. I can get comb honey in this way, and also extracted; but there must be no extracting done at this time, or no comb honey will be obtained. This is plain to all comb-honey producers.

I have another claim of economy in the small square short-frame hive; and that is in material. It takes less lumber to form a square of the same cubic contents than the long hive; less roof for same volume covered, and less bottom. All this you can figure for yourself. It is plain to be seen that you have less ground floor in a four-story house of four rooms, and less roof, than if the four rooms were in only two stories.

I should be pleased to call your attention to the following, and then I am done:

In the *American Bee Journal* of Nov. 15, page 625, E. L. Holden says, "I, in 1858, bought of Rev. L. L. Langstroth the right to use his hive, for which I paid him \$5.00. At the same time I bought two hives, both of which I still have, and have just taken the trouble to measure them. The inside measurement of the hive

is $18\frac{1}{8}$ inches one way and $15\frac{3}{4}$ the other, and $10\frac{1}{2}$ deep. The frames are, inside measurement, $12\frac{1}{4}$ and $10\frac{1}{2}$ inches. This is the common hive; the other is his observatory hive of two or more stories. The frames are of the same length, but the depth is only $8\frac{3}{4}$ inches. These frames are the very ones I bought of father Langstroth 36 years ago, and, of course, are the correct size of the Langstroth frames."

Now, if this octogenarian is correct, were not the frames the size of the short Langstroth frame? Were not the frames set across the hive and across the entrance? Who is correct? Is there not hope of a standard frame?

Will not some friend call on father Langstroth and read this statement of friend Holden's and learn for a certainty from his lips the truth? and if not that, the true and original Langstroth frame was not $12\frac{1}{4} \times 8\frac{3}{4}$, inside measurement; so that we who advocate a short frame are within the pale of truth when we claim, at least in part, to be followers of father Langstroth when we use and advise a shorter frame, and a square hive for reason of its economy.

Astor Park, Fla., Dec. 10.

[Years ago the short Langstroth frame was tested quite extensively by a large number of bee-keepers, ourselves included; and the only advantage we could discover was that they were a little lighter to manipulate and better for queen-rearing than the long frame, the two short frames making a small and more compact cluster for the nucleus. But we, like everybody else, discovered that there were just so many more frames to handle for the same capacity, and, with a very few exceptions, they were discarded for the long frame adopted by father Langstroth years ago. I have sometimes thought myself, that, if the crosswise Langstroth had been made an inch or so deeper, and adopted as a standard by Langstroth, instead of the frame now accepted as such, *perhaps* it might have been better. But after all, reports seem to show that colonies on the short frames winter no better and produce no more honey. The Langstroth utilizes to the very best advantage the standard width of barn-boards in the *hives*; whereas in the deep-frame hives very wide lumber must be used, or one or more pieces fitted together. This makes the hive either expensive, owing to the wide boards, or if of narrow boards, to a greater or less extent a patched-up hive, with unsightly cracks that will surely gap sooner or later. Taking every thing into consideration, while the Langstroth standard seems to give just as good results, both for wintering and for honey, it surely does give more surplus room on top—a very important desideratum, by the way.—Ed.]

ECONOMY IN THE PRODUCTION OF HONEY AS A STAPLE ARTICLE.

BEE-KEEPING IN CUBA, IN A NUTSHELL; RESOURCES GREAT, BUT PRICES LOW.

By Fred L. Cragcraft.

In order to correct the impressions of some of the readers of GLEANINGS who seem to think this is the "El Dorado" of the bee keeper, and

that fortunes are to be picked up in a few months, I will give a few facts in regard to the outlook.

During the season of 1891 and '92, buyers paid from 45 to 50 cts. per gallon; in 1892 and '93, from 40 to 45 cts. The season of 1893 and '94 opened at 38; later on, dropping to 35, and during the summer of 1894 prices dropped down to 20 cts. per gallon; and now with new honey coming in, dealers are offering from 24 to 26 cts. per gallon, without package; but before the end of the season prices may go up to 30, or they may go down to 20 cts.; and with sugar at $1\frac{1}{2}$ cts. per lb., and other staple products correspondingly low, and all manufactured goods exceedingly high (Spain having bestowed with an unstinted and generous hand the blessings (?) of a high tariff protection upon this beautiful but unfortunate country), it can be very easily seen that the prospects are any thing but flattering, and the only solution of the problem is by producing honey on a large scale, and economically enough to make it a safe investment.

There are certain conditions here which make it peculiarly adapted to producing honey at a small cost. There being sufficient flowers here to sustain from 200 to 500 colonies at one location, the certainty of the honey-flow, and the small amount of work required to keep the bees in condition, are factors which must be considered in counting the cost of production.

With a modern four or six frame extractor, a lively man who knows his business can throw out a large amount of honey in a day; and where there are a large number of colonies in one place the bees do not get enough honey during the spring and summer to encourage swarming to any extent; and during the "campañilla" honey-flow the bees are never strong enough to swarm; therefore it can be seen that the swarming question can be eliminated.

In order that the readers of GLEANINGS may see the rapidity with which extracting can be done by having the apiary arranged in a convenient manner, I will give a short description of the *modus operandi* in use here.

The sheds for the apiary are 13 feet wide, with a row of hives set on each side, the entrances facing out, and the hives set close up together, there being only about half an inch space between the hives, in order that the supers may be lifted off easily without being wedged in between the hives at the sides. In this manner the hives form a solid wall on each side, making it darker inside, and very few bees enter to bother a person when opening the hives, and it is also a protection in case of robbing, as the robbers do not like to enter the shed; and after buzzing around the entrance a while they will become discouraged and leave. When extracting, a man can fill his comb-cart at one place, saving both time and steps.

Taking into consideration the length of the

honey season, and having all the rest of the year to requeen, I think a man can manage seven or eight hundred colonies by having an assistant during extracting time.

San Jose de las Lajas, Cuba, Dec. 21.

[I think our readers, at least those of latter days, would like to see a photo of one of those bee-sheds to which you refer; then tell us *why* you have it, etc.—Extracted honey at 26c per gallon is about 2½c per lb. Well, if one man can with a little assistance take care of 800 colonies, perhaps he could make a little margin on even this ridiculously low price.—ED.]

RAMBLE 124.

BEULAH LAND.

By Rambler.

We learned that bee-keeping was not neglected in the old historical county of Monterey. I had on my list of correspondents a few, but they were away from our line of travel, and circumstances did not favor our going into the byways of the county. I believe, however, that the county as a whole is not a first-class honey-producer, and may rank with its sister county of San Luis Obispo, on the south, as having only a few and far-between favored localities.

I found some quite nice comb honey in one-pound sections in a Salinas grocery, and learned that it came from an apiary near the Salinas River, some six miles away. It proved that a progressive bee-keeper was laboring there with some degree of success.

After a day's rest in Salinas the ponies were called into duty again, and we circled the Bay of Monterey for many miles, and camped on the sands of the shore where again the thunder of the waves lulled us to sleep. Our neighbors in this camp were industrious fishermen in their humble hut, from whom we obtained a supply for our evening and morning meals.

We this day, July 27, added another county to the growing list we had passed through, and entered Santa Cruz (Holy Cross). We found here a dividing line of hills, not of an arduous nature to climb, but when we had climbed to the crest and looked out upon the scene beyond we were both inclined to shout "Beulah Land!" For weeks we had witnessed dry and barren plains and hillsides; but here was a valley of freshness and beauty where the fields were green, the mountains beyond covered with a wooded growth from summit to base. The transition was so sudden that the following verse came to mind:

A sweet perfume upon the breeze
Is borne from ever vernal trees;
And flowers that, n'er fading, grow,
Where streams of life for ever flow.

The town of Watsonville was nestling like a gem in the midst of the sea of green, and the people we met had a buoyant air about them which was also in sharp contrast to the deflected air that pervaded the agricultural regions

subject to drouth. We had anticipated finding fruits in abundance as we toiled northward, and here our expectations were realized. Fruits of all varieties were plentiful and cheap. Apple-orchards abounded; apples in profusion

PSHAW, WILDER! THAT'S MEAN.

on trees, in profusion on the ground. I had not seen the like of it since I left the far East. An early and opportune rain had given vegetation here a boost that made nature and people happy. Bro. Wilder looked far and near over garden-walls in hopes to see an extra early watermelon; but the festive melon had not put in an appearance, and he had to content himself with a few fresh apricots, apples, etc. We saw the busy bee at work upon the various blossoms, but did not hunt up the owner. I have not learned whether the valley is of much value for honey production; but from a passing observation I should think bees would do fairly well there. That the home market is not supplied by local producers was evidenced by the groceries having on sale the decoctions called "honey," from San Francisco wholesale houses—the usual glass jar, with fancy label and a piece of comb in liquid, supposed to be honey.

WORN CLIFFS AT SANTA CRUZ.

Had there been an enterprising bee-keeper near Watsonville it is evident that this foreign substance would have been crowded off from the market.

From Watsonville to the city of Santa Cruz we found many fine ranches, the owners having so much pride in them that the names were posted conspicuously upon fancifully decorated signs; thus, Sylvan Dell, Glen Echo, Aptos Ranch, and many others were passed. The Aptos Ranch comprised many hundred acres, with a deer-park, blooded horses, and every thing that betokened the wealth and taste of the owner, who, we learned, was C. Spreckles, one of the sugar-kings.

It was in this region we also saw our first specimens of the noble redwood trees. There is a little belt of them here, and they are truly majestic.

By a little extra pushing on the lines we made Santa Cruz just before the shades of evening fell. Our inquiries for a camping-place revealed that there were several such locations. For a quiet place to spend Sunday we were directed to the old fruit-dryer locality. In following up the directions we approached a large building, and surmised it to be the dryer. Several well-dressed people were coming from it, and inquiry elicited the information that it was not a dryer at all, but a tabernacle of the Christian Church, in which there was at the time a State Association being held. We felt that to be just the place to spend Sunday, and accordingly camped in the grove of gum-trees with the rest of the disciples. It was a pleasure to again attend services of this nature,

after quite an absence of several weeks from it. The good brethren were very zealous in their views, and one aged minister came in Sunday morning from a town twenty miles out, and arrived before some of the good people in the tents were up.

In the afternoon we strolled into the city. Santa Cruz is quite a pretentious town, of about 5000 population, and its chief industry seems to be gazing at the ocean, and bathing; or, in other words, it is a great resort for pleasure-seekers. Bathing-houses line the shore, and beyond the bathing-beach are the chalky cliffs which the restless waves have for centuries been wearing away, until caves, tunnels, and many curious formations are the result. The breakers dashing through these formations occasionally throw the spray high in the air. Our walk to town was along the cliffs, and our walk and talk was enlivened by witnessing the antics of the dashing waves.

Santa Cruz had just been enjoying its annual "fiesta." This Sunday was the last day of the celebration. The attractions of the day were feats of horsemanship, shooting of glass balls by Texas Jack, riding bucking bronchos, and a bullfight. The above sports were held in a large inclosure, and we deemed it our sacred duty to stay outside. The bullfights are more or less of a sham outside of a wholly Spanish community, and we afterward learned that this was also a sham, or a trick to draw a crowd.

A quiet crowd was gathered upon the beach, the foreign and Spanish element largely prevailing. Thus we had on this Sunday in Santa Cruz a diversity of attractions that ought to

suit the most ardent sight-seeker, and happiness ought to (and seemingly did) prevail.

DISCOURAGEMENTS.

By J. D. Fooseh.

Friend Root:—I believe that, as bee-keepers, we should report discouragements and losses as well as successes. I know to report loss is not nearly so pleasant as to report success in our business. It has been said, and truly it looks as if it were true, that misfortunes never come single. I will come forward as a bee-keeper who has been reasonably successful in the business for about 18 years; but I must say that this year has been the most disastrous that we have had during the whole of the 18 years; and not only in the bee business, but nearly all other industries failed to the extent that what we made as money, crops sold, and is being sold, fell below the cost of production. The March freeze that caused such widespread destruction showed itself in the harvesting of our grain crops. The wet summer we had told seriously on the cotton crop, which is our money crop; and, to cap the climax, cotton fell in price to 5 cts., and at times below that. This is unprecedented in the knowledge of this generation, since the war, and it is needless to say that all classes are feeling the depression from low-priced cotton. I am not disposed to complain, for an all-wise Providence can overrule all these disasters and disappointments for our good; but, really, the situation is certainly gloomy to begin to farm for another year, to raise cotton at 5 cts., which is the main money crop for the South.

As to my bees, they are in excellent condition for the winter, having stored plenty of honey to carry them through to spring in excellent condition. Had I not fed my bees after the March freeze, I should have lost at least $\frac{3}{4}$ of them, as most people here who had bees lost in that proportion. I shall try to set out another year, trusting that we shall have better success than this in all departments of business. My bees, upon the whole, gave about as good results from the outlay as any thing else that I engaged in.

I mention these facts to show that, while we may be sanguine and prosperous in various departments or enterprises, we do meet with failures occasionally, but no more nor oftener in the bee business than elsewhere. I set a large lot of cabbage-plants last spring, which were all killed, and had to contract for 2000 lbs. seven-top-turnip seed, which was all killed. I now have a contract for 4000 lbs. of seven-top-turnip seed, and can sell thousands of early-cabbage plants if I get orders for them; but it seems, of late years, that all or nearly all our success depended upon getting safely through March.

Coronaca, S. C., Dec. 1.

CHAT ON EUROPEAN MATTERS.—NO. 4.

By Charles Norman.

A correspondent writes that, in September, at a time when the bees were killing the drones, he heard tones that came out of several hives, and these tones he took to be the piping of queens. In one hive the tone was so strong that he heard it at a distance of ten feet. He opened the latter hive, but found nothing unusual. He thinks the sounds were produced by drones "molested by the bees," for "at this time they sometimes make a noise that is not dissimilar to the piping of queens."

Mr. Doolittle's excellent article on the prevention of robbing, in *GLEANINGS* for Mar. 1, page 191, was duly appreciated, for Mr. Bertrand has translated and published it in full for the benefit of his readers.

To find out to which hive the robber-bees belong, we are often told to sprinkle them with flour, etc. Instead of doing this a correspondent puts at the entrance of the hive, all along and very near the entrance, a strip of flour, so that the bees which leave the hive are obliged to whiten themselves in this flour in passing.

The present low price of honey is a source of great anxiety and complaint to the French and Swiss bee-keepers. There are numerous complaints to be found like this: "At this time the great effort of the apiculturist needs not to be directed any longer toward the increase of his crop (as to this, enough directions are given to us), but much rather how to dispose of it;" and in this direction these French-speaking apiculturists display a vim and energy which beat Mr. Dadant's "dreadful Yankees" all to pieces. At their frequent exhibitions (more frequent than in our country) they not only present their finest honey in the most attractive form, but they combine with them a regular honey-market where many visitors who would not buy otherwise are induced and persuaded to purchase, with the expectation of creating a demand on the part of the public for good pure honey. Moreover, they try all kinds of ways of transforming honey into eatable or drinkable things. They make vinegar, hydromel, brandy, and liquors of it; use it for the manufacture of chocolate and bonbons; give directions for making apothecaries' syrups, etc. As the temperance movement is known there by name only, and they are not yet up to an understanding of its noble principle at all, both laity and clergy take a deep interest in the production of the above "drinks;" and not seldom one hits upon articles written by Protestant ministers as well as Catholic priests, in which recipes for making these stuffs are given, and the urgent necessity of creating a market for their sale is set forth with genuine zeal. Allow me to cite just one instance, to illustrate the blindness with which my continental countrymen (I am a German with a little admixture of French blood) are

stricken. In a speech delivered by a noted French apiculturist we find the following: "If, regarding the food substances, our age has a well-characterized taste, it is certainly the one for alcohol and alcoholic beverages. They have been used and abused to such an extent that the general health is already affected by it; and from the chair of the hygienists as well as from the laboratories of the analysts, competent authorities announce a slow but continual degeneration of our race." Now, any logically inclined mind should, from such a premise, it seems to me, draw the inference that we had better abstain totally from the use of alcoholic beverages. Not so our orator. He distinguishes between the drinks which have hitherto been consumed and "the vinous beverages, as well as the delicately flavored and healthful alcohol that can be produced from honey," and then he goes on to tell how these are made!

How the French and Swiss apiculturists cure foul brood by means of formic acid or eucalyptus tincture, etc., I have already described—see page 788, 1894. I still remark, that, that in order to prevent foul brood, many of them place naphthaline under and about the frames.

Mr. A. I. Root, in his A B C, has some kind words for the ants, and says that, so far as his experience goes, they were never any considerable bother to his colonies. A certain Swiss bee-keeper met with quite a different experience. One day he noticed an extraordinary excitement about the entrance of a hive. When looking after the thing he observed that quite a number of ants were attacking the bees about the entrance, biting their legs, wings, and bodies. The bees, being unable to get rid of their enemies, either flew off, carrying them along, or dropped down to the ground from the alighting-board, to die there. Boiling water, applied to the ants and to their nest, restored peace.

There is an instance reported of a mule which fell victim to bees. It was tied to a tree, near an apiary. Unluckily for it, the stand under a hive broke down at this very time, and the hive was upset. The bees threw themselves upon the mule, and treated it in such a manner that it was dead before it could be led to the stable. Every thing, however, has two sides, and the report concludes with the words, "The master consoles himself, because it had become quite vicious."

The laws of a certain bee-keepers' association contained the following article: "Meetings shall not take place on Sundays." For some reason or other this section was repealed, and only one man found fault with it, and withdrew. How different the customs of different peoples are!

In conclusion, let Mr. Gubler, a prominent bee-keeper of the canton of Neuchatel, relate what came to pass at one of his apiaries:

"Last year a lover of sweets tried to help himself from one of our hives. But he came off

badly for that. Probably being a novice in the art of robbing a colony, he directed his efforts toward the very worst of our Cyprians, and selected a frame from the center of the hive at that! Finding, no doubt, more stings than honey, he was obliged to abandon his prey and run away in a hurry. We found the frame lying at the side of the hive, with a cupful of frozen bees. Fortunately the queen had remained with the colony, which has not suffered much by this nocturnal attack."

St. Petersburg, Fla.

THE EUCALYPTI, OR GUM-TREES.

PROF. COOK DIRECTOR OF FARMERS' INSTITUTES
FOR SOUTHERN CALIFORNIA.

By Prof. A. J. Cook.

Dear Editor of *Gleanings*:—You remember the blue-gums and less common red-gums of Southern California, which are, next to the beautiful peppers, the most conspicuous and vigorous shade-trees of this region. The species of eucalypti are desirable here, for they become large trees in a very brief period (four or five years), and go down to water, so that they are independent of irrigation. There are about one hundred species, many of which are exceedingly beautiful, and so this tree is of no mean importance to the people of this sunset land. Like the acacia, there are many kinds, as rich in their beauty as in their variety, and some, at least, are very valuable as honey-trees.

Last week, while conducting a farmers' institute at the wonderfully beautiful city of Redlands, I was entertained by Mr. A. K. Smiley, who, with his brother, owns "Smiley Heights." This place is a marvelously beautiful illustration of what can be accomplished by the art of the skilled landscape-gardener. About eighty species of eucalypti help to form these wondrously varied pictures that charm every one who visits "Smiley Heights."

I have been surprised, the past two months, to find how much honey my bees have gathered every bright warm day in October, November, and December, and they are many. The bees have been busy, and have not a little honey. Upon examination I find the chief source of the nectar is a winter-blooming eucalyptus, which Prof. McClotchie, one of our best California botanists, tells me is *Eucalyptus longifolia*. The bark of this tree is smooth, and so it is a much pleasanter tree for roadside planting than is the common blue-gum, or *Eucalyptus globulus*. The constant peeling of the bark of the latter, which is the most common eucalyptus yet planted in California, makes it untidy, and, in so far, undesirable for roadside planting. The *Eucalyptus longifolia* has long leaves, which doubtless gives it its name. Indeed, the leaves

are much the form of leaves of mature trees of *Eucalyptus globulus*. You remember the peculiar leaf habit of the blue-gum. The early leaves are oval and bluish; while later, as the tree becomes older and larger, the very long green leaves replace the earlier and more curious leaves. This *E. longifolia* has very showy and beautiful flowers. They are creamy white, and the long numerous stamens are very conspicuous. A curious conical cap also falls off the bud as it opens, which adds to the interest of this honey eucalyptus. The fruit is also conical, or top-shaped, and so is attractive after the flowers fade. The tree, like nearly all California trees, is long in bloom. It had been blooming since October, and is certainly good for three weeks yet. That it is a rapid grower is shown in the fact that a two-year-old tree is seventeen feet high. It is very desirable that our bees be able to secure honey during the winter months, and so I wish to urge upon California bee-keepers the wisdom of setting or planting this *Eucalyptus longifolia* as we would the basswood in the East. It is most desirable for roadside planting for other reasons, and must become a valuable acquisition to our bee-keepers. As yet it is a rare tree. Mr. L. L. Pond, of Riverside, writes me that it is very rare there. I find only a few about here, and I have noticed scattering trees at Pasadena and a few at "Smiley Heights."

Another eucalyptus, probably *E. rostrata*, is said by Mr. Pond to be very fatal to bees. It blooms earlier in the season, and Mr. Pond says he has taken gallons of dead bees from beneath the blooming trees. He says a neighbor who has an irrigating-flume beneath the blooming trees has had the holes so stopped up by dead bees that it interfered very much with his work of irrigating. This is very interesting, and I shall give it personal attention next season. It would seem that *E. rostrata* might well be superseded by *E. longifolia*.

There are various reports about the insecticidal properties of the eucalypti. It is reported that the blue-gum keeps the mosquitoes away, and is deadly to many microbes; and a merchant of Los Angeles reports, so I learn from Mr. Abbot Kinney, our best authority on these trees, that the foliage placed among clothing is an effective preventive of moth ravages.

I have been appointed by the University of California as Director of Farmers' Institutes of Southern California. This is exactly the soil for grand meetings. There is so much of ability and culture among the ranchers that the papers are very able, the discussions very free and sprightly, and the attendance and interest are remarkable. I speak at each institute of the value of bees in horticulture, and receive a very hearty response to my propositions.

Claremont, Cal., Dec. 27.

[We, as bee-keepers, will rejoice over the appointment of Prof. Cook as Director of Farm-

ers' Institutes; for that means that the bees will receive a fair share of recognition, and Prof. Cook of all men in a public meeting seems to have a happy faculty of breaking down antagonism against our pets, and of creating an interest in their behalf.—Ed.]

MICE IN BEE CELLARS.

THE DAMAGE THEY DO; HOW TO POISON THEM.

By C. Davenport.

Mice in bee-cellars do more injury than is often suspected. From a good deal of experience I know that a very few mice, if the hives are so that they can get in or at them, will often ruin a good many colonies. When I built my two outside bee-cellars, six years ago, I tried, and thought I had made them mice-proof; but they soon got in. Bees seem to draw and attract mice, and it is pretty hard to keep the vermin out of a bee-cellar. Of course, it can be done; but I will venture the assertion that they can get into 29 out of 30 bee-cellars as they average. Wire screen can be used to keep them out of the hives; but this is a poor plan, for bees that are confined are apt to become restless and excited. Wire netting is used that will not confine the bees but exclude the mice. This is considerable work and expense; and, besides, if the hives are so that the mice can reach them they will gnaw and scratch, trying to get in; and if they are not able to get in they will do nearly if not quite as much harm as if they did, as many bees will come out, and the mouse then helps itself to the choicest part of as many of them as it wants; and it is not only what they eat, but their gnawing excites the bees so that a good many of them leave the hives, and die around in the cellar; and I think this is often attributed to other than the real cause. If this is kept up for three or four months it is apt to cause poor luck in wintering.

The hives in both of my cellars are fixed so that mice can not reach them. This can be done without much work or expense. My hives are set in tiers. The lower tiers are supported about a foot, or a little more, up from the cellar bottom. I would have them like this, mice or no mice. I know that in my cellars, and I think in all cellars, it is better to have the lower tiers up from the cellar bottom; but in cellars that have tight board or cemented floors this may not make any difference. Neither of mine has any floor except the ground. I set the lower tiers on two pieces, 4x4. These are placed about 10 inches apart, and are held up by driving a stake into the cellar bottom at the end of each; and if the 4x4's are long, and the hives are piled pretty high, it will be better to have a stake under the center of each 4x4. I nail two or three narrow pieces of boards, across on the under side of the 4x4, to keep them from spreading. On the top of each stake

I place a piece of tin, about 8 inches square. These tins can be held in place by driving a nail through the center of each into the stake; but this is not necessary; for, after the 4x4 are placed on top of them, they will stay all right. If the whole is a little away from the walls this will keep mice from getting at the hives, as a mouse can not walk bottom side up on a piece of tin. Old pieces of sheet iron or zinc would answer for this as well as tin.

I will now give those of you who have your bees in the cellar so that mice can get at them a plan by which you can get rid of them without their doing much if any harm to the bees. You will need three or four old saucers. Tin covers, or any small dishes that are not of much account for anything else, will answer for this purpose. In one put some cheese that is mashed up fine; in another put some fresh lean pork that is chopped up fine; and if beef is handy, put some of that in with the pork. In the other, put some honey; and if you have both dark and light, it would be well to give them a dish of each kind. Try to suit the taste of all. Season the contents of each dish with arsenic well mixed in; and if these dishes are set around in the bee-cellar, and the contents renewed every two or three weeks, mice will not damage the bees much. It does not cost very much to feed them this way, as one meal is all each one cares for; and if any of you do not care to kill them, it is far cheaper to feed them in this way without the arsenic than to let them help themselves in the hives all winter.

Some of you will probably think it is not necessary to give them such a variety; but in order to have them let the hives alone, I assure you that it is.

Now, probably some of you will also think that I have exaggerated the damage mice do; but I will again assure you that I have not; and in this locality, at least, they are often the cause of heavy winter losses.

Southern, Minn., Dec. 3.

FIVE-BANDED BEES.

BEES FOR BUSINESS: A FEW POINTS WELL MADE.

By J. J. Hardy.

They are very pretty to look at, but every experienced bee-keeper and stock-raiser knows that the fewer points of excellence you strive to attain in breeding bees, horses, cattle, or any thing else, the nearer you can breed up to your ideal of perfection; and not only so, but every added point is detrimental to the others. The *prettiest* bees that I ever saw were those that came in so heavily loaded that they would fall and roll over each other in front of the hive. The prime essential in a honey-bee is its honey-gathering qualities; therefore I breed first for

the best honey-gatherers; then after they have stored the sweet nectar I like to have a divide without bringing on a regular pitched battle. Give me the best honey-gatherers that are good-tempered, and I will be satisfied. Every one must admit that these are the essential traits of a good honey-bee; and whenever you attempt to breed in an additional trait you must do it at the expense of one or both of these.

BEE-SPACE.

After trying different distances, from one-fourth of an inch to three-eighths, I settled down on one-fourth of an inch as the correct bee-space. I use double-top-bar brood-frames; and where all the spaces between top-bars, frames, and supers are $\frac{1}{4}$ inch, I have neither brace nor burr combs.

RAISING QUEENS IN FULL COLONY.

I have tried raising queens in the same colony with another queen by placing the old queen on four or five brood-frames behind the division-board, with queen-excluder, without any chance of exit from the hive. The entrances to these hives were on the side. They built queen-cells readily, and raised queens. But the queens, instead of going out to mate with the drones, seemed to have a mania for killing the old queens, which they did, in many instances, going through a double set of excluders on the division-board, to reach them. But they could not, or did not, get back to go out to mate, and soon disappeared. And the others, too, disappeared in a short time without even laying any eggs. I lost a good many bees by this experiment, but I learned that it is best in bee-keeping, as well as other things, to experiment always on a small scale. I used a single-story hive for these experiments.

Lavonia, Ga.

BEE-PARALYSIS.

REASONS FOR THINKING IT IS NOT CONTAGIOUS.

By S. A. Shuck.

Editor Gleanings:—I have just read Mr. T. S. Ford's article, page 871, on the above subject. In speaking of bee-paralysis Mr. Ford says, "Beyond all doubt it is infectious." And in your footnote you state that it is "positively settled now that the queen can and does transmit the disease."

While the circumstances in Mr. Ford's apiary are such as to cause him to decide so positively, yet there are so many contingencies in matters of this kind that there is much room for error in judgment. If the disease is infectious, why is it that a severe case of it does not infect a part or the whole of my apiary? Yes, if it is infectious why is it that a sudden flow of nectar causes it to disappear altogether, as in Mr. J. P. Israel's case?

While I have noticed a few of these paralytic bees in a portion of my colonies nearly every

every year since obtaining my first Italians, in 1878, there have been but few cases of sufficient severity to require special attention. In the winter of 1882 I had 52 colonies in a temporary cellar, made expressly for wintering the bees. Two of the strongest of these colonies became restless early in the winter, and continued so until set out in the spring, at which time both of them were affected with paralysis. As the spring advanced, the disease grew worse; so that, when the flowers began to yield nectar, they were only about half the strength of average colonies. But at this time they began to recover, and the disease soon disappeared.

The winter of 1884 being very severe, I lost most of my bees; and, having no better place to put the hives and combs from dead colonies, they were stacked up in the yard, and closed up to keep out robbers and moths. After the weather had become quite warm, I discovered that what I considered my best colony was robbing from the combs from dead colonies. This colony persisted in robbing these combs until I had them occupied with other bees. During this time they became affected with paralysis, and began to dwindle away. I removed their queen and gave them another. But by the time they were compelled to turn their attention to the flowers for subsistence they were too weak to be profitable for honey-gathering. At this time they began to recover, and became a fair colony before the season closed.

In 1892 one of my most promising colonies became suddenly affected with this disease. Soon after discovering their condition I removed the queen, intending to give them another; but the bees died off so rapidly that the colony soon perished outright. A part of their combs were given to other colonies, and these were replaced with combs containing bees and brood, thus restocking the hive, and without any noticeable ill effects.

Quite a number of other cases have appeared in my apiary from time to time, but not of sufficient severity to materially affect the working strength of the colonies. If the disease were infectious, my apiary would surely have been ruined by it several years ago. As it is, my bees, so far as I can see, are as active and healthy to-day as they ever have been.

From my observations I have concluded that, in some instances, this disease is the result of a poisoned condition of the honey, and that the poisoning results from incipient fermentation—not that all honey with a slight tendency to ferment is injurious to bees, but that honey in this condition will readily absorb the poisonous effluvia from dead and decaying bees or other decaying matter in the hives. Then, too, I believe that, in many instances, the honey becomes actually sour enough to cause the disease; and I fear that this is the trouble in warm climates such as that of California and the Southern States.

It is no uncommon thing for me to find sour honey in a few hives at extracting time, except in very dry seasons. In several instances fermentation had proceeded far enough to cause great blisters in the cappings of well-sealed combs. Colonies that produce honey of this nature are the ones that have paralysis.

Here is where the many contingencies mentioned above present themselves; and a number of questions naturally arise, of which the two following are, perhaps, of most importance:

What sours the honey?

Why is the honey in one hive sour, and that in a dozen, twenty, fifty, or more, in the same apiary, and gathered at the same time, in good condition?

The answer to these questions is found in the fact that an occasional colony is found, that, for some cause, unknown, I think, to apicultural science, does not possess the ability to properly ripen their honey in average honey weather—especially if the nectar is very thin. As the temperature increases, this weakness becomes more apparent; so that, with a temperature up in the 90's, with an excessively humid atmosphere, such colonies are really worthless; and in a large apiary, at such times, several colonies may show this weakness in a less degree.

Here, I think, is the sequel to the cause of paralysis in warm climates. If the source from which the nectar is obtained is one that naturally produces an inferior quality of honey, and the ingathering is at a time when the atmospheric conditions are such as are mentioned above, a careful examination of the combs will reveal the fact that, in a large per cent of the hives, numerous minute gas-bubbles exist in the honey. If allowed to do so, the bees will seal this honey up; and, although it may be left in the hives several days or even weeks, its condition grows worse, as is shown by the gas-bubbles which become more numerous and larger; and when this honey is thrown from the combs by the extractor it presents a frothy appearance.

During the past fifteen years I have experienced two seasons that gave me considerable trouble with this kind of honey. Bees reared from food of this nature show a decided tendency to the disease in question, even here in Central Illinois; and the longer these conditions exist, the worse the disease becomes, owing to the increased deterioration of the food and the weakened condition of the nurse-bees. This condition continues until the colony perishes; or if a fresh supply of healthy food is obtained, it shows signs of recovery with the first generation of brood thereafter.

Liverpool, Ill.

[I admit that there are a good many contingencies in matters of this kind, and that there is much room for error; but it seems to me you have overlooked a very important factor—local-

ity. As I have often said, this disease has not appeared to be serious at all in the North. It is what it may do and has done in the *South* that we have been considering. I never knew it, in fact, in the colder climates, to cause any particular trouble. An occasional colony, for instance, will show that it is not in normal condition. Investigation shows that it is affected with paralysis; but it does not seem to be infectious, and, if left alone, will go off of itself; but the case does not dispose of itself so easily in the *South*. Possibly soured food has something to do with it; but note this fact: In many instances the removal of the queen effects a cure notwithstanding the bees are in the same hive, on the same combs. This one fact alone by itself, to say nothing of other corroborative evidence, seems to show that the trouble is hereditary rather than one of food; but no doubt good food, like good diet for human ills, would go far toward doing away with the difficulty.

I am very sure that the course of queen-breeders in stamping it out as soon as it appears is the right one. Now, this disease is surely, in warm climates, making serious inroads, and the only way to check it is for queen-breeders—not for their own sake, but for the sake of their customers—to stamp it out of their own yards on its first appearance. So far all of them have held up their hands, signifying their purpose to carry out this policy. As it will entail some expense in the loss of a colony, the ready response of the queen-breeders to agree to this is as generous as it is kind.—ED.]

JAKE SMITH ON BRACE-COMBS.

HE REPORTS AN INTERESTING CONVERSATION CONCERNING THEM.

Mr. A. I. Gleanings—dear Sir:—Jim Short's a good-hearted fellow, but he has some queer notions. But then, a good many people's that way. One good thing about Jim, he never gets mad if you side agens't him. He was over the other day, and Zed had been readin' in your paper about burr-combs. Beats all what that boy thinks of your paper. Why, he reads it through from cover to cover, and then reads the cover. Well, he was a tellin' Jim how it told to get shet of 'em.

Then Jim turned to me, and, says he, "Does your bees build brace-combs?"

"Course they do," says I, "whenever they have a chants."

Then Jim luffed one of his hearty lafs, and, says he, "That's what comes o' gettin' so many kinks out o' books. Now, my bees don't have any book-larnin, and they don't build any brace-combs. Not a blame comb but honey-comb. What kind o' comb is brace-comb, anyway? Do they make it just out o' beeswax or what?"

"Why," says I, "brace-combs is beeswax like any other comb, only it's the little pieces they build in between the top-bars; and when they build between the top-bars and the supers, why, that's burr-combs."

"That's it," says Jim; "you git in so many new fixins with your top-bars and supers and sitch that the bees jist has to start in some new way to keep up. Now I want to know if every-

body that has these new fixins is agreed in tryin' to stop brace-combs."

"I guess they be," says I.

"No," says Zed, "not all. There's Doolittle, one of the smartest in the lot, and he says he wants his bees to have brace-combs—wants 'em for ladders to climb up on; thinks they commence work upstairs sooner."

"Now that stands to reason," says Jim; "you go to work and put on another story for them, and then you don't build no stairs for 'em to climb on, and they go to work and build ladders. Now, there's my house. You know the kitchen floor's two feet higher'n the sittin'-room floor. Now, how would it work to have that two feet to climb up and down all the time with no steps? Hard on the women-folks, hey? Well, you see I jist decently put some steps there; and if I hadn't a done that you wouldn't blame

WHAT ARE THEM BURR-COMBS ANY WAY.

the women for puttin' boxes and things for them to climb up and down on, would you now? And that's jist what the bees do too. They build things to climb up on, soze they won't have to split their legs a straddlin' so far."

"Say, Jim," says Zed, "how many steps is there between your kitchen and sittin'-room?"

"Let's see," said Jim; "each step's about 8 inches rise, ain't it? That would make two steps 16 inch high, and then it would be 8 inch more from the top of the step to the sittin' room floor. Yes, they must be jist two steps. But what difference does it make how many steps they be? Course, they must be steps enough to

git up, no matter how high. What makes you ask, anyway?"

"Oh! nothin'," says Zed, "only I was just a thinkin' if it wasn't so high you wouldn't need so many steps. If the two floors was on a level it might be still better for the wimmen folks; and if they couldn't be exactly on a level, but only about 8 inch difference, they wouldn't need any step."

Jim hawhawed right out. "I guess you've got me, Zed," says he. "I believe in my soul you're right. Make the upper story so fur up they can't reach it, and they've got to build steps; but make 'em so close they can reach from one to the other, and they don't need any steps. You're a great one, Zed. Well, I must be a gettin' along to do my chores. But I believe Zed's about right."

NOTES OF BICYCLE TRAVEL.

AT CHICAGO; ON THE WORLD'S FAIR GROUND;
DR. PEIRO.

By E. R. Root.

Before leaving Platteville, in view of the awful Wisconsin roads that I had gone over I decided to take the train for Chicago direct, and therefore left on Monday morning, and arrived in the city toward night of the same day. The following morning I took the elevator (on 57 Fifth Ave.) for the top floor of one of those sky-scrapers in which is located the office of the *American Bee Journal*. I found Bro. York busy at his post, preparing to mail the next issue of his paper. On asking me how long I would stay I told him that I was one day behind again, and I should have to go that night. He would not have it so any way. I had disappointed him once by giving him only a short call; and now that I was in his possession he intended to keep me at least over night. Resistance was useless, and I meekly acquiesced.

He proposed that we take a run over to the World's Fair Ground for an afternoon's outing, to which I readily agreed, for I was very anxious to see what was left of the most beautiful conception that ever came from the human mind. Having some business down town I told Mr. York I would meet him toward noon. The tire of my rear bicycle wheel had given out, so I stopped at the Chicago office of the Overman Wheel Co., and on their guarantee I got a new tire put on. While the wheel was in the repair shop I ran over to Mr. Newman's, at 147 South Western Ave. I found him in his office, reading the morning paper; and for an hour or more I had a very pleasant chat with the former editor of the *American Bee Journal*, and now manager of the Bee-keepers' Union. As our readers know, he had sold out the journal on account of ill health, and is now confining himself solely to the work of the Union and the sale of bee-keepers' supplies. The season had

not been an extra good one. It started out well; but the railroad strikes, whose center of operations were here, chopped it short off. His customers, fearing they could not get their goods, went elsewhere.

Physically, Mr. N. was looking much better than I expected to find him. He had had very severe sieges of the grip; but he seemed to be master of the situation.

After an hour's pleasant chat I left, to join Mr. York. In the afternoon we took a train for the great World's Fair, or what was left of it. As we neared the place I had a kind of feeling that I ought to see those beautiful buildings looming up once more. But, no; most of them are gone, and that, too, the very best. On going through the gate where we used to pay 50 cts., now open to the public, every thing seemed to have changed. The terrible demon, Fire, had done its work. Midway had turned into a residence street, where just a year ago there was bustle and hustle—indeed, a pandemonium of sights, things, and persons.

Where, oh where! were the Manufactures and Liberal Arts Building? Over yonder were some lofty towers of framework of what might have been, probably, the great building. Tons and tons of massive framework attached to other framework standing, hung dangling carelessly in the air, and seemed ready to drop any moment; and great masses of steel bars were twisted and distorted into every imaginable shape. Bridges were burned; in fact, every thing was so fearfully changed that my heart was sad in comparing the mind's-eye picture of a year ago with what I then saw. The lagoons were there, of course, but the beautiful railings were damaged, and some of the bridges were gone. The Horticultural Building, and the Illinois State, both to me of the least interest of all, were left standing, and over yonder was the Art Building, which, of course, had been put up permanently, and is now a museum.

The grounds in general seemed very much smaller now than the best and greatest of the structures were destroyed, and every thing seemed so changed that it was hard to tell where one was "at," the old landmarks having been almost completely obliterated. Here and there on the banks were gondolas, turned bottom upward, bleaching in the sun. They were of no practical use then, and nobody wanted them. The Esquimaux ponds were gone entirely save the hollow dry spots that marked their location.

Tramping about as we did over the obstructions, Mr. York was considerably tired; for, unlike myself, he was not used to long-distance traveling. We accordingly made our way as best we could over the piles of rubbish, to the Art Building. This stood in perfect condition as it appeared a year ago, and it was refreshing to look upon something that was still left of the Great Fair in a perfect state of preservation.

It is a museum now, and seemed to have a collection of a little of every thing from nearly all of the buildings of the fair. A number of pieces of statuary were still in the building, very near their old positions, and everywhere numerous other exhibits that I remembered. But in contrast with a year ago it was disappointing. Along late in the afternoon, footsore and tired (yes, I was tired too), we made our way to the station, and were soon back in Chicago. After a few minutes in the office we took the train for Englewood, a suburb of the city, where Bro. York lives. On the train we were joined by Dr. Peiro, the one who writes those interesting articles for the *American Bee Journal*, under the title of "Doctor's Hints." I wish I could show you his picture; but he is so modest that I was unable to get it. Never mind. I will get even with him somehow. Evidently he is a man who practices what he preaches, for he seems to be the picture of health; full of life and fun, it is indeed a pleasure to know him. I believe in his profession he makes a specialty of lung and throat troubles, and yet by his writings it is evident he is well up in all that pertains to his profession.

That evening, before supper, we took a look over the apiary of the *American Bee Journal*, situated in the rear of Dr. Peiro's yard. The neighbors at Bro. York's, if I remember, were afraid to have them there, and so the doctor kindly offered to "take them in." Mr. York very modestly professed to know little or nothing about bees,* and wished me to look them over, and assume the role of *instructor*. A smoker was procured, and we proceeded to open up the hives.

"Why," said I, "Mr. York, you have got supers on at this season of the year." (You will remember it was the first of September.) "I would take them off, for surely you do not need them now."

"But they are gathering honey *now*," said Mr. York.

"Impossible," said I.

"Indeed, they are."

On pulling off the covers, I saw sure enough that the bees were putting honey into sections.

"What in the world can they get around here, almost in the city?"

"I can not tell you," said Mr. York.

We opened two or three hives, and every one of them seemed to be busy piling in the surplus. In the mean time Dr. Peiro came out and enlivened the proceedings with his easy-flowing wit and banter. After looking over the bees, Mr. York called my attention to the lawns, as we neared Mr. York's home. I presume there were a good many acres in reach of these bees; and the constant mowing and sprinkling allowed the white clover to spring up and yield nectar out of season; but on sampling the honey

that evening at the table, there seemed to be something besides white clover which was certainly present. It had a beautiful minty flavor, and in my estimation—and I think perhaps in that of Mr. York—it was as fine honey as can be produced anywhere in the world. A swamp near by it evidently gave the mint taste, so pleasant. I have always considered the Colorado alfalfa, since I first tasted it, the best; but this is fully its equal.

That evening Dr. and Mrs. Peiro called upon the Yorks. Somehow or other I felt as if I were out of place, in my knickerbocker suit, dusty and dirty; but I soon forgot my external appearance in the pleasant chat that followed.

The next morning, having had a delightful sleep and good breakfast, I called at the office of the Overman Wheel Co., secured my wheel, and took the train for Toledo. The bicycle at this point was resumed; and on reaching home, 110 miles was made in 9 hours. Thus ends my long trip on the bicycle to the Mississippi, through Michigan.

MRS. HARRISON EN ROUTE FOR FLORIDA.

By Mrs. L. Harrison.

On the 15th of December I left my home at Peoria, Ill., and turned my face in the direction of the sunny Southland. While in transit I looked carefully for the sight of homes of the busy bees. In Tennessee I saw an apiary of considerable size, arranged with care and order, in movable-frame hives; and another, more southward. The weather was like summer, and heavy clothing unbearable at Pensacola, Florida.

I took passage in a schooner to cross the Gulf of Mexico. We passed leisurely along by the Navy Yard, Fort Pitkins, the light-house and life-saving station, and I thanked my God that I was a citizen of a Christian land, whose government looks after and provides for the safety of her people who do business in great waters. The winds were kind, and the next day we arrived at the place of our destination, St. Andrews, Florida.

Here roses of every hue were blooming in great profusion; pear-trees in full leaf, loaded with a second growth of fruit. While a resident was showing me over his lovely grounds, and directing my attention to the difference in the spray of the Satsuma oranges, he remarked that his bees had stored only 40 lbs. of surplus honey to a colony, which he considered only a third of a crop. This apiary is located near the Bay, so that half of the flight of the bees is over salt water.

*Such modesty in an editor who gets out such a good bee-journal is quite inexcusable.—Ed.

Later.—To-day is the last day in the year, and we look in vain for the beauty which greeted us on our arrival. During the night of the 27th, 28th, and 29th of December there were heavy frosts, and on the 28th ice formed two inches thick, while the thermometer registered 15° above zero. Orange-trees and lemons look sickly, and pear-trees are brown and sear.

St. Andrews, Fla.

DAMPNESS IN BEE-REPOSITORIES.

Question.—I went to my bee cellar to-day and found things quite wet with collected moisture—so much so that the sawdust on the floor was saturated, and a post in the center, and also the inside of the roof, was quite wet, caused by this dampness. The bees appear very quiet, and are apparently doing well so far. Will this dampness do any particular harm, or accumulate to a sufficient extent to injure the bees before it is time to set them out in the spring?

Answer.—Many seem to suppose that a cellar in which bees are wintered should appear absolutely dry in all of its parts; and if it does not, or shows a condition of things similar to that described by our correspondent, they become fearful of the final results, often taking the bees out too early in the spring, or putting them into another cellar or room exhibiting more dryness. It will be noticed that it is stated that the bees "appear very quiet." Now, I wish to say to each and every one, that, so long as bees are quiet, or very quiet, no matter where they are, whether in the cellar, in a room above ground, or on the summer stand, they are wintering in the best possible condition, and should be left undisturbed, no matter if the place where they are is dripping with moisture, or so dry that you may fear the bees are suffering from want of water. Quietness is the essential quality for safe wintering, for with it always comes the least consumption of stores, and with a minimum consumption of stores comes the least possible exhausted vitality and the greatest longevity during the spring and early summer days. Under such circumstances I have had individual bees by the thousand, in single colonies, live from the first of September till July first of the following year, or for a period of ten months, this being known by a change of queens on or about the tenth of August. On the other hand, I have had colonies which would not quiet down during the fall, and bees which were hatched in such colonies the latter part of September were worn out with old age, and died before the first of February, not having lived to exceed four

months. From all the experience of the past, I am convinced that the temperature of the bee-repository has more to do with the safe wintering of bees than any other one thing, and especially is this the case where the repository is affected with dampness as was the one our correspondent describes. Should the temperature in such a repository sink to near or quite to the freezing-point, it will be found that the bees will no longer be quiet, but will become uneasy, and go to roaring, and running out of their hives, should such a temperature continue long; but if the temperature can be kept at from 42° to 48°, all things will continue as they are at present, unless some disturbing element enters in besides moisture.

That I might better tell you regarding this matter I have just been to my bee-cellar, where I consider my bees wintering well, to see how I found things. I have 80 colonies in it, to where I have usually had only from 50 to 60, and I find that the extra number of colonies give off more moisture into the air than has usually been the case in years past—so much so, that, on this second day of January, I find the inside of the bee-cellar fully as damp, or wet, as I presume many would call it, as it generally is by the first of March; while, instead of the temperature staying at about 44°, as has usually been the case, it now stands at 47°, or within half a degree of this all the while. Well, how wet do you find the inside of the cellar? The sawdust on the floor, the furthest from the door, is so wet that I can nearly squeeze water out of it, while near the door end it is barely moist enough to be pliable in the hand. This sawdust has been unchanged for two weeks; but after the examination, I have spread evenly over the floor another flour-sackful, this covering up all dead bees and the sawdust there when I went in. In two weeks I shall put on another sackful, and in this way the floor is kept sweet and nice. The roof, or upper ceiling, of the cellar is covered with flagstone, as the older readers of GLEANINGS will remember, and I find that the moisture has condensed on these stones sufficiently to be running down on the under side (very much as you see the steam or moisture from your room trickle down the inside of the window-panes in the kitchen when you are boiling vegetables for dinner), to an extent sufficient to form little puddles of water at the foot of the stones where they rest on the mason-work walls. The moisture condenses on the inside of the door, and runs down in the same way it does from the stones, as the door is a painted one; and, in spite of there being four doors in the entranceway, this inside door is the coolest place in the whole cellar.

Now I think I hear some one say, "Why, that cellar is absolutely wet;" but such is not the case, for the hives and all about them (they do not touch the wall or floor of the cellar) appears as dry as in summer, and will so long

as the colony of bees remains alive inside. But should any colony die, then the combs and honey take on moisture very similar to the door and flagging; and if the colony should die soon after being set in, the combs would become quite moldy by the time the bees should be set out; but as I have not lost two per cent in this cellar of late years, not many combs thus become wet and moldy.

Perhaps some of the readers of GLEANINGS would like to know how the bees appear. They are so quiet that I stood with a lighted candle in front of one colony, holding the candle within fifteen inches of the bees for three minutes, and I could not see that a single bee moved at all; but a little breath from my mouth upon them, at the end of this time, made them all raise their abdomens and thrust out their stings, and in a minute more they were crawling about, some nearly ready to fly at the light, when I withdrew from them and looked elsewhere. Some of the strongest colonies have nearly as many bees hanging below the bottom of the combs as one-half of your hat-crown turned bottom up would be, while others show just a row of the points of the abdomens standing out all along between the bottoms of the combs, while still others are up so far between the combs that no bees are to be seen from the bottom of the hive. To any lover of bees, the first and second described are so enchanting to look upon that it becomes almost bewitching, and it is with reluctance that I leave the cellar every time I go in. To look on a cluster of from two to three quarts of bees hanging below the combs, like a swarm in July, all perfectly motionless, and each bee lapping over its neighbor like rows of shingles on the roof, right in the middle of the winter, with the mercury outside at from 10 above to 15 below zero, is a sight which will dispel the blues, and a sight which is apt to give almost any one the "bee-fever." At least, I find that I have a touch of that disease myself at this time, although I have kept bees now for 25 years.

Borodino, N. Y., Jan. 2.

DO DRONES CONCENTRATE ON ANY PARTICULAR HIVE?

Do drones ever concentrate on any particular hive, and eat it out of house and home, as it were, during the working season or any other time?

JERE. LARUE.

Perris, Cal., Dec. 19.

[We never knew the drones to concentrate upon any particular hive, although it is possible that they may do so. If you were a beginner we might suggest that possibly the killing-off of the drones at the proper season when hon-

ey stops coming in would bring about the effect you describe. The bees push them out of the hive, and they concentrate, as a matter of course, around the entrance. They certainly look hungry enough to eat the colony out of house and home.—Ed.]

STRONG FOR THE TEN-FRAME HIVES.

I have been much interested in the discussion of the eight vs. ten frame hives. I give you a little of my experience in this section in using the two side by side for three seasons.

I got more honey and better swarms each year from the ten-frame hive, from one-fourth to one-third difference, with that much more winter loss in the eight-frame, for which I set 50 out of the eight-frame to the ten-frame hive. Most bee-keepers are discarding their eight-frame hives for the ten, in this section.

For extracting I tier up two and three stories high, using eight frames above in a ten-frame body to save so much uncapping. For comb honey I tier up with supers as room is needed. Swarming is harder to control in eight-frame hives—more inclined to swarm, and not so large as from the ten-frame hive.

We have had three very poor seasons here for bees. I have only 125 stands at present.

Washington, Ind., Dec. 3.

S. D. COX.

A POOR YEAR FOR W. K. BALL; THE ADVANTAGE OF EXTRACTING IN POOR YEARS.

We had a very poor season here; still, I think my bees did well. I took 13,000 lbs. of extracted and 1500 lbs. of comb honey from 100 hives. I think that is good for a poor year—don't you? I find there is a big advantage in extracting, over raising comb honey, in a poor year. I sold my old stock of bees last winter, and went to California (near the town of Hanford), and got 100 colonies of Cyprians, with a mixture of Italians. They are good workers, but fearful stingers. My comb honey is not as white and nice as common. I lay it partly to the poor season and partly to the strain of bees. I am going to try the Carniolans next year. I understand they make very nice white comb honey. I don't like that greasy-looking comb. Is it the Italian or the Cyprian that makes the dark-looking comb? I received 20 Carniolan queens from Mr. Lockhart, and expect 4 more. They are very nice.

Reno, Nev., Nov. 12.

W. K. BALL.

CARP CULTURE, ETC.

Mr. Root:—Do you remember the pond under my greenhouses? Well, you put a good deal of enthusiasm in me when I read your "Carp Culture;" so, two years ago, I put in 35 carp, 4 to 6 inches long, and now there are thousands of them. The old ones are 10 to 14 inches long, and we can drop in a hook at any time and catch one. I had not tried to catch one till this week. I don't care what others say, as for me and my house, we rate carp a No. 1 fish. When I was in Medina I thought A. I.'s carp-pond

looked neglected. We made another pond last week, and will stock it with carp as soon as spring opens.

GEO. M. KELLOGG.

Pleasant Hill, Mo.

[I am glad to be able to tell you that our carp-pond does not look as sad as it did. Just before Christmas, during the fine open weather, we cut a ditch alongside of the bank of Champion Brook, 400 feet upstream, to a little dam across said brook. Then we put in three-inch tile, put a little dam across the brook, and the carp-pond was filled up right speedily with nice clean rain water that fell on the ground in winter time. Just as we got the whole thing finished, and working to my satisfaction, a zero freeze came on, and now we have pure rain-water ice fully eight inches thick. In fact, it is ready now for the ice-house, and the carp have plenty of room. I am glad you pronounced them a good table fish.—A. I. R.]

FENCING POULTRY "OUT;" HOW HIGH MUST THE FENCE BE?

Mr. Root:—Are you not mistaken about hens not flying over netting one foot high? We have Brown Leghorns, and they fly like hawks—are for ever on the move in daytime, and are the most prying, inquisitive things that I know (that wear feathers).

D. W. DICKINSON.

Hickman, Ky., Dec. 24.

[Friend D., we have had quite a little experience in the matter, and we find that one foot seems to answer every purpose with our large breeds of fowls, and we have some small ones also. Of course, this is for fencing them *out* of any particular locality. We once had a strawberry-plot near the poultry-house. It was put out originally for raising Haverland *plants*; but before we knew it we had a big crop of berries. The hens found them and commenced to work on them before they were even red. We put a strip of poultry-netting around the whole inclosure, only one foot wide. Of course, it was put up as high as we could put it without allowing the hens to crawl under. Not a berry was touched afterward. Some of the Brahmas walked along the fence, and looked over; but none of them got in. Of course, you can not fence fowls *in* with any such fence; and I presume the arrangement will answer only where they have unlimited range. Perhaps they reason this way: "Why should we take the trouble to climb over that thing when it is such an easy matter to walk around it?" They would accordingly walk around the corner; but, not finding the strawberries, they got their minds on something else, and walked off in another direction. I tried those same strips of one-foot poultry-netting to keep the neighbors' hens away from some peas. I had not enough to go clear around the peas, so I extended the fence two or three rods beyond the patch, in both directions. It served the purpose of warding them off about as in the former case—that is, it stopped them from going straight from the barn to the pea-patch; but occasionally a fowl that was out in the fields, on her way home would get into the peas. It must be remembered that poultry will seldom meddle with peas any way, where they are properly provided for otherwise.

Ernest suggests that 18-inch netting is a little better, and two feet still surer. His experience was in putting such a fence around his dooryard, to keep his neighbors' fowls away. Of course, this will be a little different. Where one man keeps a lot of fowls, and is pretty close up to a neighbor who does not keep any,

a division fence to make the chickens stay at home, especially if said chickens are in a town where they are pretty closely circumscribed any way, would need to be a little higher. Then it is to be remembered that chickens are like cows and horses in regard to getting out of an inclosure. A certain flock may become so educated that they will do very unusual things. Notwithstanding, the narrow strips of poultry-netting oftentimes serve very important purposes. We have a lot of iron rods sharpened at one end, and a little coil made at the other, to get hold of easily. These can be quickly thrust into almost any ground so as to make the strip of netting just right when it is hooked on the ring at the top of the iron stake. You can put up such a guard against the fowls almost as easily as you can chase them away, and then the job is done with until your crop is ready to be gathered, then pull up your stakes and roll up your netting until it is wanted next time. A 150-foot strip of netting, one foot wide, costs now only 67 cts.—A. I. R.]

ROBBING SICK PEOPLE.

Mr. Root:—I have just read your article on Electropoise, and was much interested, as we have an instrument that just answers the description of it, but it is of a different name, "Oxydonor Victory," manufactured, patented, and invented by one Dr. H. Sanche, 264 West Fort St., Detroit, Mich. The price is \$25. It is exactly the same in appearance as Electropoise. Whether it is a humbug or not I can not say. My mother had a very estimable and intelligent lady nurse who heard of Oxydonor, and went to Toledo and investigated the same. She personally interviewed some of the most prominent business men of the city who had used it. She became interested, and took an agency for the same. Mother gains some; and father, who has not done much work for some time past, does a good deal now. I myself cured a case of bowel trouble, and it was of considerable standing. It may be that we all would have got better had we not used it. If it is a swindle it ought to be exposed, for it is an exorbitant price. I am not a scientist, and could not analyze it should I take it to pieces; hence I write to you.

I have not written this for publication; but should you find the machine a fraud, and want to, you may use this; but please suppress my name, as it would only make hard feelings, as the agent here investigated it for us.

If I can help in any way I shall be glad to do so. My mother has paralysis. X. Y. Z.

[Friend Z., one test will apply to all these things. If the thing you describe has any virtue, then a new force or power has been discovered; but scientific men, our intelligent doctors and teachers, know nothing of any such discovery. What you tell us only illustrates again the *awful* fraud and swindle that these men are putting upon the public. The fact that prominent business men indorse it, again illustrates the credulity of the people at large. It *must* be imagination. It can not be any thing else. The very fact that they charge \$25.00 for the trifling bauble is one big evidence that it is a fraud. It is exactly on the same principle as hanging something about your

neck for a charm, or nailing a horseshoe over the door, or having little heathen gods stuck all over the house, as the Chinese do to ward off calamity and disease. With the general intelligence and science before us at the present time, people of intelligence ought to be ashamed of themselves for accepting such logic. I suppose you know that people afflicted with paralysis and many other diseases, when they are thoroughly aroused, oftentimes break away, as it were, from the disease. They have sometimes thrown away their crutches under the influence of a bottle of some kind of medicine; and yet had the bottle contained water, and they did not know it, the result would have been just the same. Many thanks for your concluding words.—A. I. R.

In the issue of *Electricity* for Jan. 9 we find a further considerable expose of Electropoise. We have room for only the concluding sentence:

Every religious paper in America might well keep standing in a conspicuous place in its columns the words of Dr. Holmes: "Quackery hobbles along on two crutches: the one is the superstition of women; the other, the indorsements of clergymen."

EIGHT extra pages this issue.

WE have quite a number of good articles awaiting their turn for insertion.

UNDER "Seasonable Questions" is a valuable article on bee-cellars—that is, how to *know* when the bees are doing well. This is a troublesome question for beginners, and even some older in the business.

HEAVY rains are rejoicing the hearts of California bee-keepers. Given a certain number of inches of rainfall, and the honey crop is assured for that State; this year the conditions, if I am correct, are met. Last year little or no rain fell, and the consequence was little or no honey.

THE new *American Bee Journal*, as it came to our office shortly after Jan. 1, was a pleasant surprise. It has been changed from a 32-page small to a 16-page large size. The printing and binding, of course, as usual, are excellent, and the selection of matter is also of the highest order. If it can maintain the pace that it has set for itself (and York will make it), the "old reliable" will boom.

G. M. DOOLITTLE, in the *American Bee Journal*, has an interesting article on large versus small apiaries. He says, and very truly, that the results from large yards are not as great in proportion as from small ones. He sees large reports from apiaries of not over 50 colonies, but not from four times that number. It is like every thing else I suppose—some lines of business will pay good returns on a small scale;

but on a large one, failure is the result. There is much in the man and the location.

You will remember that I said we had great hopes of the granulated sugar and honey giving better results than the ordinary Good caney made of confectioners' or powdered sugar and honey. We are just receiving responses of queens sent to Australia some time last fall; and while the results are not all that we could ask, they are very much better than from any former attempts of late. The only difficulty seems to be now that the granulated sugar is too coarse, and rattles about in the cage, and interferes with the bees. We are just corresponding with the view of getting a small paint-mill, to grind the sugar and honey into a perfectly soft paste. I have an idea that such a mill would cause a more perfect union of the honey and sugar.

THAT GREAT FREEZE IN FLORIDA. AND ITS EFFECT ON BEE-KEEPERS.

WE have just enjoyed a very pleasant visit from Wm. A. Selsor, of Wyncote, Pa. He had just come from an extensive business tour of some 3000 miles throughout Florida. He had been all over the State just previous to the great freeze, and all over it again just after it. He reports that all the beauty of that remarkable State is gone. Every thing seems to have been killed from one end of the State to the other; and the mangrove—one of the main stays for honey—has been so thoroughly killed that it will take it three or four years to recover. Although the bee-keepers will get honey as before from palmetto, their large crops will be cut down very materially until the mangrove can begin to yield. There is desolation in the orange-groves, and they are characterized as "slop-tubs" by reason of the carloads of decaying fruit. As to what the Weather Bureau might have done to prevent this, see High-Pressure Gardening elsewhere.

DOOLITTLE AND THE FIVE-BANDED BEES.

IN the *Progressive Bee-keeper* Mr Doolittle has a very fair and interesting article replying to the statement of the editor (which I copied on page 877), that the five-banders can not be produced from Italian stock. He holds that the Italian is *not* a pure race; and as it is liable to sport, especially in the number of yellow bands, it is perfectly feasible to produce the excess of yellow without the aid of Cyprian stock; that he raised bees with more than three bands before Eastern bees were ever brought to this country. In relating how he and Mr. L. Hearn developed the original so-called five-banded stock, he adds that they are not only beautiful, but good workers, and gentle, though he admits that they are less hardy for winter when compared with the darker stock.

I have personally seen in his own apiary some

of Mr. Doolittle's choice yellow stock. They were perfectly gentle; and although it is *possible* that other blood might have crept in, in view of Mr. Doolittle's statement to the contrary, and the care characteristic of him, it is improbable. But I do insist that some five-banders are vicious, and poor workers; and the conclusion forces itself upon me that there are *some* careless breeders, and perhaps not as conscientious as they might be in keeping out the Eastern blood, for it is *so easy* to breed yellow from this race. The yellow stocks at present in our yard came from a number of breeders, and the progeny of the queens vary greatly.

WINTERING; WHY THE INDOOR PLAN GIVES
THE BEST RESULTS IN ONE LOCALITY AND
THE OUTDOOR IN ANOTHER.

In the *American Bee Journal*, in the department of Queries and Replies, the question is asked, "Do you prefer the single-walled or the double-walled hives?" The majority of respondents vote for the first, but not one of them seems to mention the part that locality plays in the matter. In fact, they all live either far south or far north. Of course, those in the southland would prefer the single-walled. Those who live where the winters are pretty cold, as a general rule prefer the indoor plan, because the double hives hardly give protection enough. But where the winters are moderate, and in some others where great quantities of snow fall, the double hive, I am sure, gives the best results. In our locality the outdoor plan surely does best. We sometimes have a couple of weeks of weather when the thermometer registers 10 degrees below zero; but more often it is open, with several weeks of fairly warm weather sprinkled in. It is *then* that the *cellared* bees get uneasy, fly out on the floor, and die by thousands; and it is *then* that *outdoor* bees get beneficial flights. Where the winters are continuously cold for the most part, the cellar plan gives the best results, because it (the cellar) can be kept at an even temperature, or nearly so. This means a light consumption of stores and comparatively few bees dying on the floor. Since writing the foregoing a well-written article on bees in cellars has come which I indorse—see p. 59.

L. L. LANGSTROTH.

I have before alluded to the fact that our aged friend and benefactor is in rather destitute circumstances, especially since the death of his son-in-law; and although there have been many calls on our bee-keepers for contributions—in fact, so many that I almost dread to speak of any more—I do think it behooves us each and all to remember father Langstroth. Perhaps the younger members of our fraternity of bee-keepers do not know about these things as well as we older ones do. By the way, some years ago quite a number of the veterans agreed to set

aside a certain sum of money each year, as a remembrance, or, perhaps we might say, a New Year's gift to our veteran benefactor. How many of us have kept sacredly this promise? I know of one man, and his initials are A. I. Root, who waited till the 10th of January before sending in his offering when he ought to have sent it the 1st. Perhaps it may be something of an encouragement to others to say that we have been paying Mr. Langstroth \$50.00 each year, for a long time past, and we have felt happy in doing this much. I have made these remarks thinking there may be others who would really enjoy giving our old friend a pleasant reminder that his services are gratefully remembered by bee-keepers. The *American Bee Journal* has been keeping this matter before the people for some time past. Will the other bee-papers do what they feel would be right and proper in reminding their readers of the debt we owe?

A. I. R.

THE BEE-KEEPERS' UNION.

THE Tenth Annual Report of the Bee-keepers' Union is before us. The General Manager, in commenting on the past work of the Union, says:

I am glad to state that the Union has everywhere exerted such a soothing influence that now the enemies of the pursuit are very cautious in commencing a suit against bee-keepers. Lawyers have read in their Law Journals reports of trials which have resulted disastrously to the complainants, leaving them to pay the costs, and they generally discourage such litigants unless they have well-filled pocket-books, and they discover a chance to make liberal fees. Even then, many of them will not undertake a case which gives no promise of success. Quite often they advise their would-be clients to send to the Bee-keepers' Union for documents; and when such are received and read, the arguments of Judge Williams and the decision of the Supreme Court of Arkansas are so convincing that they quite willingly nurse their wrath, and permit their bee-keeping neighbors to enjoy their rights and privileges.

One or two cases are on hand, and advice has been rendered, and the result will be given in the future. In the line of adulteration, the history of the Hunt honey-adulteration case is given, with the details of which our readers are already familiar. The financial statement is as follows:

FINANCIAL STATEMENT.

Balance, as per last Report.....	\$721 71
Fees from 311 members for 1894.....	311 00
Expenses for the year.....	\$1,032 71
	254 20
Balance, Dec. 16, 1894.....	\$778 51
Donation, L. M. B.....	5 00
Total balance on hand.....	\$783 51

The *American Bee Journal* for Jan. 3 contains an article from G. W. Demaree:

I want to suggest that the proper thing to do is to elect a new set of officers for the National Bee-keep-

ers' Union. I think a change, from time to time, is best for all such institutions.

Let all sentiment be laid aside, and let each member vote for some intelligent "bee-man" (our sister bee-keepers have a higher mission than is found in court decisions); properly distributing the number to be elected throughout the country as justly as is practically possible.

As to any change pertaining to "General Manager," that can be safely left to the judgment of the members. I can see no reason for any change in that respect, as the office of "General Manager" is hedged about by a board of directors—the president and vice-presidents. As one of the "old board," I shall positively decline to act in the future. I want to see a change.

Another thing I want to suggest. 'Too much money in the "treasury" is a temptation to lawsuits. I regard the Bee-keepers' Union a temporary concern. When we have obtained from courts of repute a sufficient number of decisions to put bee-keeping on even grounds with other pursuits, each bee-keeper must then do his own "lawing." I have practiced the profession of law, and know whereof I affirm. There is a specific stage of civilization that leads men to resort to the law as a mode of warfare against their enemies. No "union" should encourage that sort of civilization. This world—not this country alone—is becoming full of "unions," and "trusts," and "combines," and "societies," of every earthly description, and there is a cataclysm ahead, or the "watchers" of the "signs of our times" are mightily mistaken.

There is a good deal of truth in what he says, and we commend the article to our readers. It has seemed to me several times that the work of establishing precedents in law, so nobly and well done by the Union in the past, is nearly at an end; and as the extract from the General Manager says, there is less trouble now from jealous neighbors than formerly. It seems to me that the Union should do more in the way of hunting out suspected cases of adulteration—in fact, assume the aggressive—that is, employ detectives to follow up a few of the unscrupulous city dealers, for instance. Surely there are funds enough in the treasury to do this work.

THE EXPERIMENT AT THE MICHIGAN EXPERIMENT STATION, OF FEEDING BACK.

In the *Bee-keepers' Review* of Dec. 10, Experimenter Taylor reports having fed two colonies to fill out unfinished sections, for the purpose of determining the amount of loss or gain. The following is the table as it appeared:

Net wt. of sections adjusted.	Amount fed.	Amount of unfinished product.	Net gain.	Gain per cent.	Pounds fed for one lb. gain.
41 28½	106½	110½	69½	65.3	1.53
	112	99½	65½	58.4	1.70
69½	218½	205	\$135½	61.8	1.61

In summarizing on the result, Mr. Taylor says:

By a simple process of calculation, taking the value of the material used and the market value of the product, it will be seen that the profit is more than 50 per cent and this would have been consid-

erably increased had all the sections been partially filled at the beginning of the experiment.

I understand how he arrived at his conclusion, but it seems to me the figure, 50 per cent, gives a wrong impression. Let us glance for a moment at the table. By running across the figures at the top, and stopping at the last item, it is shown that, for every pound of unfinished honey, it was necessary to feed about 1½ lbs. of honey. The same item just below for the other hive, shows the proportion of 1 to 1¾. Mr. Taylor says, "The profit is more than 50 per cent." Now, I do not see it in that way. In the first place, there was the labor; and in the second place, the bees were probably stimulated to the rearing of brood—such brood as would probably be of no use to the colony later on. It seems to me the question is, which would bring more in dollars and cents—the extracted honey fed in the liquid form, plus the unfinished sections, both as separate items, or the total amount of finished product in one item, as the result of feeding? According to the Honey Column in this issue, extracted honey of good quality brings at wholesale 7 cts., and comb 12. Taking the figures for one hive which Mr. Taylor fed, there are 41 lbs. of unfinished sections, which we will say ought to bring on the market at least 8 cts. There was 106¾ of extracted, which was fed back, which ought to bring 7 cts. The total for the two items thus would be \$10.75. The amount of unfinished product for the same hive, in feeding back, was 110¾ lbs., which would bring, according to the same price current, 12 cts. per lb., or \$13.29. Subtracting \$10.75 from \$13.29 would leave \$2.54, which would represent the gain in dollars and cents; or, when reduced to percentage, 23½ per cent, instead of over 50 per cent, as Mr. Taylor makes it. But this \$2.54, it seems to me, is largely offset by the labor of feeding. May be I am mistaken; but I really can not see any great gain from a dollars-and-cents point of view. But Mr. Taylor's feeding back was, I am of the opinion, more favorable than it ordinarily is. Take the case of Mr. A. F. Unterkircher, for instance, of Manchester, Mich., about 70 miles southwest of Mr. Taylor's residence. It will be found in full in our issue for Feb. 1, 1886, page 101. He fed back 175 lbs. per colony to 20 colonies for 35 days, and got back only 62½ lbs. of finished comb honey per colony; in other words, he fed nearly three pounds of extracted for every pound of comb honey secured; or, to carry out the dollar-and-cents comparison—for every 20 cts. worth of *extracted* honey fed, he got back 12 cts. worth of *comb* honey. He says further: "Thus the consumption for the 20 colonies; in the secretion and forming of wax scales, and for brood-rearing, evaporation, etc., is the enormous total of 1650 lbs., or 82½ lbs. per colony. . . All this [stings, etc.] is certainly enough to disgust one in feeding, to say nothing regarding the loss in the operation."

WHY PEOPLE ARE OUT OF WORK.

SOMETHING BOTH ENCOURAGING AND DIS-
COURAGING.

Dear friends, I am moved to write this because of a little recent experience. Some of you know, but perhaps not all, that in our saw-room we have saws to cut across the grain. These are called "cut-off" saws. Then we have saws to split boards lengthwise of the grain. These are called "rip-saws." One is all right for the ripping business, and the other is all right for the cut-off business; but to change them about, neither would work at all. Oh, yes! you might crowd a board lengthwise a little way on a cut-off saw, and *vice versa*; but it would be like hitching a team to the back end of a wagon instead of the front, to do work. Well, now for the illustration:

There was a man in the saw-room, who, if he were given boards square in shape, or something near square in shape, would continually make a mistake and push them against the saw at right angles from the way they should be pushed; that is, he did not seem to know whether he was sawing with the grain or across it. When I heard of it I remonstrated with him. I told him I could hardly believe it possible that he, a grown-up man, should even *once* make such a blunder as that. He excused himself by saying that others did the same thing frequently. I have not learned whether this is true or not. I told the foreman of the room, when we were discussing the matter, that, in my opinion, the man who does such a thing even once should be sent home, and never permitted to come into a shop again where machinery is used. The above may be rather severe. Perhaps it is; but one whose mind is not on his work to the extent that he does not know whether he is pushing his board lengthwise or sidewise, I should say that he by such act of indifference or half-heartedness, literally *cuts off* his chances of making his way in the world. It is just this very thing we are considering that makes the difference between a man worth 10 cts. an hour and one worth 25 cts. an hour. You may say that everybody makes mistakes sometimes. Yes, some kind of mistakes. But did you, my friend, ever in your life, hitch a horse to the back end of your wagon, and start off, instead of hitching it to the front end? My illustration is, perhaps, a little exaggerated, but it shows what I mean. Now, this man of whom I am speaking is or has been a special friend of mine, and one whom I should be glad to help. When his shortcomings have been reported I have taken his part, and talked with him, and afterward said I was sure he would do better. When he did not do better I began to study into the case, and this has come to light: He is naturally full of boyish spirits, and is much given to good-natured jokes and pleasantry; and he carries this thing so far that he is very apt to be making fun during his work. We have had trouble in the saw-room by certain ones indulging in throwing blocks at each other. Notices have been put up, requesting that this thing be stopped. But even right in the face of these notices I saw this man throwing a block at one of the other men. He explained it by saying that the block was thrown at him, and that he simply threw it back again, and *it happened* to see only the last part of it. Now, this may be some excuse, but it is not a sufficient one. A grown-up man with a family to support should be above every thing of this sort—that is, during working hours. Some people do not seem to be able to comprehend the fact that almost all kinds of work nowadays require *careful, thoughtful, earnest* attention. The men who get good pay, and who are mak-

ing great strides in their profession, concentrate all their energies—all their *attention* and *thought*—on the work in question. Let us take another view of the matter.

I believe we have now the reputation of making pretty fair work—I will not say the best in the world, for every little while—in fact, almost continually—some customer (sometimes a customer from clear across the ocean) is calling our attention to little defects in our work. A few days ago one of the endless chains in the machinery that makes our sections broke a link. A new one was put in, and the machine was supposed to be all right. Mr. Calvert happened to pass by, however, and he discovered the bolts of beautiful white basswood were not passing squarely through between the dovetailing saws. One end of each bolt was ahead of the other. It was only just a "lettle," as old Yankees would say; but that "leettle" made a great part of the sections grooved too deep on one end, and not deep enough on the other. The men who were running the machine neglected to make very careful tests after the breakdown, to be sure the work done was exactly as before the break. When we hold our councils—that is, the members of the cabinet of the A. I. Root Co.—it is the same old thing over. "Oh, I wish we knew where to get real careful, accurate men—men of *intense devotion* to the work that is intrusted to their charge!" Now, please do not all of you write to me, saying that you are just the chap we are after, and that you want to come here. If you are just the chap we are after, you would not be out of work. People would be watching for you, and bidding for you, and may be quarreling about who should have you. I know, for I have grown gray in this sort of thing. Sometimes I have been tempted to say, "Oh, why is it that God made so many worth so little, and only a few worth so much?" But, hold on, God did *not* make us so. We did it ourselves, and we are *doing* it ourselves. The man who has good common sense can stop his foolishness and play, and attend to business if he tries hard. He can, if he *cares* enough about making a success in life, and the chances are that he can do it at home, right where he is. You see, the successful bee-keepers and the successful berry-growers and the successful men anywhere, and they are the earnest, keen, hard-working people. They do not always work hard with their muscles, but their brains are ever on the alert to discover better ways, and to achieve greater perfection. Now, it is not because these heedless people do not know what nice work is; for if they want to *buy* any thing they are oftentimes the first ones to complain of something that is not what it ought to be. We all know when we are properly served by the rest of the great outside world; but a great many of us do not *care* very much whether we serve other people honestly and well or not.

This little sermon is written on New Year's day; and if it meets the eye of some one who is out of a job, or is likely to lose a job which he already has, may God rouse him up to recognize and realize what I have been telling him; and may the Holy Spirit help him to see his faults as others see them. My friends, I too am guilty of poor work. I am guilty of half-heartedness and of slipshod ways—that is, at times I am. I sometimes fear, however, that I am oftener guilty of being too vehement and exacting because others around me seem to be so indifferent to what is going on before their eyes—yes, to put it plainly, so *stupidly* indifferent to their own interests; or, to put it in a sadder way still, to the interests of their *wives* and *children*, and others depending upon them.

After the above was dictated, the following

came to hand from our good friend Geo. M. Kellogg:

The reason I wrote my "want" ad. (p. 33) so sarcastic was, I am so bored by men who claim to be gardeners, etc., when they know but *one thing*—that is, to laze around and kill time. I just turned off a man to-day, after 2½ days' of work, who came and recommended himself so highly that I really thought he might be a good help. I would not give such a man his board. I would rather take a green boy, and teach him how to work. I am down on fossils in human form.

Pleasant Hill, Mo., Dec. 29.

ON THE WHEEL.—LA CLEDE CO., MO.

There are a good many peculiar things about Missouri; that is, they have different crops, and different ways of doing things, from what we have here in Ohio. The great staple seems to be corn; and the rich black soil, full of humus, for the most part, seems to be especially adapted to corn. Now, with such immense crops of corn, the price gets very low; and in a good many places the crops are a good way from railroads; therefore, to use up as much as possible of it, a great deal of pork is raised. The wire fence that troubled me so much to get over was one of the pig-proof sort. As there are immense tracts of forest, or, rather, scrub-oaks (for the greater part of the trees are a peculiar kind of oak of small growth), and these oaks furnish most seasons immense quantities of acorns, to use up this great quantity of "shack" the pigs—especially those belonging to poor people—are allowed to run at large. The consequence is, the farmer who raises crops must fence the pigs *out*; and so they have fences with barbed wire very close together down near the ground—so close, indeed, that many of them are chicken-proof as well as pig-proof, unless the chickens jump and get through the wide spaces a little higher up. In running my wheel over the dry leaves through these trails in the woods I often ran into droves of pigs. By the time I conclude, however, that they are not going to be frightened at the wheel, as the horses, cattle, and mules are, the leader of the drove gives a peculiar grunt of astonishment and fright, which is the signal for a general stampede; and if I do not slow up, I am sometimes in danger of getting rolled into the leaves among the pigs. Well, where pig-growing is such an immense industry there are great quantities of pork thrown on the market; and in order to furnish a *balanced* ration (ham and eggs) great quantities of poultry and eggs are produced. In fact, Missouri ought to be able to furnish ham and eggs enough for at least a part of the great wide world. The women-folks have a great deal to do with poultry-raising; and friend Abbott's bright spicy poultry-talks at the farmers' institutes have made him quite a general favorite with the sex. It won't hurt him any, for he is a good man, and always remembers the faithful little wife who so well looks after the comforts of his neat little home in St. Joseph.

These great cornfields are a splendid adjunct to the poultry business—especially the turkey line. Turkeys, you know, ramble over miles of territory. One of my brother-in-law's neighbors has a flock of slate-colored turkeys num-

bering over a hundred. He said they started out in the morning like a regiment of soldiers, taking the fields and woods, and every thing that came before them, each turkey marching perhaps twenty feet from its neighbor. He said they went away every morning, and generally came in about an hour before sundown, keeping up the same line of march in all their raids. I told him I should certainly have to go over to his place to see them, and I happened along just at the time specified—about an hour before sundown. They were just emerging from the woods, in a long line, all abreast. As they went over the pasture-lot, every cricket, grass-hopper, bug, and worm, was pretty sure to be detected by their keen sharp eyes, and you could see them do their work as they moved forward. Of course, they get into the cornfields some; but I believe it is generally considered that they do enough good in their march to atone for the corn they take, for corn is cheap down in Missouri.

But even with the great numbers of turkeys domesticated, there seems to be still a field for more, for wild turkeys are even yet quite abundant. They live, I believe, mostly on corn and acorns. In fact, so plentiful are they that they often mix, and the eggs of wild turkeys are sometimes set and hatched under the tame ones. They grow up with the rest very much as if that were the way they had always done; but when the wild turkeys fly over them on their way south they are very apt to catch the fever, and burst the bonds of domestication, and soar aloft with their wild untamed brethren.

The man who owned the turkeys, finding I was greatly interested in sinkholes, such as the country abounded in, told me there was quite a tract, several miles away, where the ground had suddenly dropped down forty or fifty feet, leaving steep or even perpendicular sides all around the inclosure. The road used to run through this piece of forest, and a man rode over on horseback only an hour before the sink occurred. As the rest did not seem to be particularly curious about such phenomena, I decided to hunt it up on my wheel. After various meanderings through the woods and across the clearings I discovered that I had got beyond the spot. Many people seemed to know but little about it, even though it was in their immediate neighborhood; and they speculated as to what "that fellow on the wheel" wanted of that large sinkhole, anyway. Some thought I was prospecting for minerals. At length I found a little log house in the wilderness, belonging to the man who owned the property where the ground had dropped down. Nobody was at home but the woman of the house. It was getting toward night; and darkness in a locality where it kept one busy to get through by daylight was not the thing to be most desired. She said I was to follow the road down to a wheatfield. Then I was to go straight through the wheatfield, and I would find the road again on the other side. When I got there, "straight through" seemed to be a pretty difficult matter to manage. In searching for the road I got off into the thick and tangled forest, and lost my bearings; and as the sun did not shine I could not even tell which way I came from. I was lost in the woods, and obliged to drag my wheel, and pull it through the underbrush. No matter which way I went, the bushes and vines grew thicker. I pushed for the top of a little hill, thinking I might see some signs of human habitation in some direction; but it was all unbroken forest. I could not discover in any direction any thing that looked a bit like the path or the wheatfield I had left. It may seem a trifling thing for a full-grown man to acknowl-

edge his weakness, and to ask direction from on high, just because he has lost his way in the woods only a little way off from human habitation at the worst. I felt weak and tired out in working my way through the tangled brush; and, almost before I knew it, that little prayer burst forth—"Lord, help!" Almost as the words were on my lips I stooped down to get a better view away off through the bushes and underbrush. In one direction I could see quite a distance; and at the end of this view a little patch as big as one's hand showed something that looked as if it might be a log house; and the words, "O Lord, I thank thee," followed almost as swiftly after the appeal for guidance. Before I reached the log house I struck a trail that led me to the door. There I found that I must turn around and go right back, for I had just come in from the very neighborhood of the sunken half-acre. I do not think it comprises more than a quarter of an acre—perhaps a little more all together; but the sight of it fully rewarded me for all my toil. The largest trees in the forest had gone right square down until their tops reached but little above the ground where I stood. I managed to slide down through the sand and dirt until I came to a point choked up with bushes, briars, trees, dirt, and stones. It seemed as if an opening had broken through and let every thing run down into it until the trees, etc., stopped the hole up. I got right down into the very crater; and then it occurred to me, what if my feeble weight should start the thing going once more, and I too should go down, down, who knows where? I confess the thought of it made my heart beat a little faster as I climbed up the steep sides through the loose dirt and stones. I found the road that had been broken suddenly off where the ground went down. This drop, too, like the others, was near the summit of a hill. Can some geologist or somebody else tell me why it is the hills instead of the valleys that suddenly give in, down here in the Ozark Mountains? Has this any thing to do with the reason volcanoes burst forth from the summit of the highest mountains?

Of course, I had many pleasant visits in Lebanon, the county-seat. It is a very pretty town. The stores are neat and attractive; and as business is dull, goods are sold, many of them, at very close margins. The merchants are vying with each other in getting the trade of the country people, and may be they know their own business better than an Ohio wheelman can tell it to them. But I want to venture a suggestion. If some merchant in the town of Lebanon would put up a watering-trough, so the farmers could water their horses in front of his store, giving them that beautiful "electric" (?) water, it seems to me it would be a bigger advertisement than all the signs he could put up, or all the advertising he could do in the county papers. If I am correct, there is not a place in the whole town where horses can be watered—that is, no public watering-place. A little out of town there is, it is true, a sort of millpond where horses can be watered by driving right down into the mud. My brother-in-law told me that this pond arrangement was a recent improvement. Where is the Humane Society down in Missouri? By the way, there are no such watering-places in the whole of Missouri—that is, none that I found—like those we have here in Ohio. In our own and adjoining counties where I have traveled with my wheel we find substantial watering-places every four or five miles in almost every direction. These are more frequent, however, in hilly countries, where springs furnish perpetually running water. Through the level parts of our State, town wells with good nice-work-

ing pumps are found in the center of most of even the small towns. Let us now go back to Lebanon.

All through the southwestern part of the State of Missouri there is a sort of general agreement that hitching-posts should not be placed in front of stores. In fact, you seldom see a team standing in front of a store at all. When farmers come in from the country they hitch their horses near the church or to the fences in the outskirts, and then travel on foot to the stores. When they get ready to go home they can, if they choose, drive up in front of the stores to load in their purchases. On one occasion a friend missed a train because he had to drive out of town to find a place to hitch his horse. This whole matter is fixed by ordinance passed by the town; and I was surprised to hear one of the teachers at the farmers' institute pitch into hitching-posts. The only reason he gave was, that it made the town look untidy; and hitching-posts, where horses gnaw them, afford means of communicating disease from one horse to another. Now, I am sure this whole matter can be managed. In Medina we have iron hitching-posts that horses can not gnaw, and I know a good many of the country people feel bad the way they are being used. I asked Robert which of two towns would get the trade if one would furnish convenient places for hitching teams in front of the stores, steps for the people to get out on the sidewalk, and public watering-places where horses could drink, while the other town furnished no such inducement. He said the farmers would almost in a body patronize the town that tried to make them welcome in the ways mentioned above.

Terry said, at one of his recent institutes in Indiana, that the merchants of a certain town provided a good dinner for all the farming friends who came to the institute. When the farmers expressed some surprise at this, one of the men of the town got up and said: "Look here, neighbors, when we happen to be out in the country at dinnertime your doors are always thrown open; your wives bring out their best things laid away for company, and you never think of asking us to pay. It is a pity if we can not return the compliment when you have a meeting here in town like this, once a year."

Now, that is the sentiment exactly. Farmers throughout our country have been having a tough time of it. Sad will be the day when the people of our towns and cities think it behooves them to look down on the farming community, or to laugh when drouth and flood prove disastrous to the crops. United, we stand; divided, we fall.

When the people found out how curious I was about caves, sinkholes, etc., somebody told me there was a natural tunnel not ten miles from the county-seat—a place where a horse and buggy could be driven through under ground nearly a quarter of a mile—a tunnel of God's own making through the hills. Few people, however, could tell me much about it. One man said that, instead of being a quarter of a mile long, it was only 75 or 100 feet through it. He said, too, there were stalactites and stalagmites like those in Salt-peter Cave. I suggested that it was a natural bridge, but he said it was not a bridge at all; it was, rather, a tunnel through the hills, and a tunnel that crooked and turned.

The weather turned cold, however; reports came from home that Ernest was laid up, and Mrs. Root said I had seen enough holes in the ground for one visit. So I reluctantly bade adieu to Laclede Co., Mo.; but it made me feel a good deal as it did in leaving Tempe,

Arizona, without even visiting Superstitions Mountain. By the way, after I left Superstitions Mountain a band of explorers found a great gold-mine somewhere near its summit, and speculators are taking their victims right into the mountains and exhibiting them gold that stands right out in plain sight—not quite in plain daylight, but plain enough so that thousands and thousands of dollars are being put into it. Am I sorry I did not stay long enough to help discover the gold? Not at all. God has not called me to develop gold-mines. If they could be separated entirely from the gambling and swindling and robbery that seem to be so invariably an adjunct, I might like to see them; but *my* field is the strawberries, the beautiful honey, soft water from artesian wells, and all these things that are awaiting man's touch and skill: and how we may secure them by our labor is more in the line, I am sure, whereunto I am called.

He hath filled the hungry with good things.
LUKE 1:53.

The words of our text are taken from that wonderful speech of Mary, the mother of Jesus; in fact, it is a part of her salutation to Elizabeth. I hardly need explain to our readers that this promise means something more than simply satisfying our bodily appetites, or that the good things mentioned are simply something to eat. When we are tired out with the cares and worries of the day, and when hunger comes as the result of honest, earnest labor, we enjoy taking our food. But this joy and this satisfaction that we experience would be a very poor feeble thing to *live* for. It may be that there are people who think more of what they shall eat and drink, and who spend more thought in making provision for good things to eat and good things to drink, than any thing else; but I am sure the most of us would pity such a human being. I confess I feel a little ashamed of myself, sometimes, say after having had an enjoyable wheelride, because I take so much comfort in partaking of food and drink. I am glad of one thing, however—I very seldom take either food or drink without first thanking God for it. When I am away from home, a great many times there are no thanks given—that is, at least, no general audible thanks before we take food and drink; and in public places it is not to be expected that all should unite in recognizing the great God above before each meal.

While I am dictating these words we are only a little way past New Year's day. The words, "Merry Christmas" and "Happy New Year," have scarcely died away from the streets and in the homes, and wherever we go. They are coming even yet through the letters; but I am afraid our people are almost too busy here in our work to remember to return these kind wishes and salutations. But we think of it, nevertheless. It is this "I wish you a happy New Year" that impressed me to take up this thought.

A good many times, especially during this year of 1895, I have tried to analyze this "happy New Year" expression. What does it mean? A great many times the well-wisher adds something about prosperity; but financial prosperity does not make a man happy. If he has been working hard, and the prosperity

comes as a result of his labor, then I confess there is a kind of satisfaction and peace in seeing things come into shape. He has his reward for doing his duty. In my department of the work here I almost always have a great lot of things on my mind. I sometimes say to myself, "Oh, dear! this thing *must* be attended to before the day passes." But the day does pass, a great many times, when it is not done. More important things crowd. But if I keep on trying, and asking God for grace and strength to tackle each new difficulty, by and by I get at least a good many of them done. Then I feel glad. The one who neglects and neglects, and *continues* to neglect, is not very likely to have a happy New Year, nor a happy year of any sort, for that matter. In fact, I do not know of any one thing that makes a man more miserable than to keep neglecting and putting off things he ought to do.

Now, this expression in our text, "good things," means substantial things. Why, everybody knows—at least, it seems to me everybody knows—the good things spoken of in the Bible are the most substantially good of any thing there is in the whole world. We are enjoined on every page to "seek first the kingdom of God, and his righteousness." Of course, it is not worded that way; but we all know the attitude the Bible takes; we all know the spirit of it. It enjoins us to be unselfish; it enjoins us to find our satisfaction and happiness in working for the general good of humanity—in striving to lift up, to restore faith and courage to the faint-hearted or to the weary soul. Man's wisdom—I do not mean manly wisdom (because manly wisdom would be God's wisdom); but the fashionable worldly wisdom—would be to take notice of the rich and the great, and to seek for their favor, but to overlook the downcast and the discouraged. The mother of Jesus opens her mouth in thanksgiving and praise because God has seen fit to send his Son into the world, among the poor and lowly. He has passed by kings and princes; he has disregarded the crowned heads and those who sit in palaces; he has sent his greatest gift, the gift of his Son, into the world, to the homes of the poor and lowly, even to the birth in the manger. Now, dear friends, when we say to somebody, "I wish you a happy New Year," what thought have we in mind? do we wish such a person worldly prosperity that he may wear fine clothes, and be spared from the toil and drudgery of every-day life? God forbid! There are some overworked fathers and mothers who ought to take a little respite; they ought to have a little more time for the easy-chair, and perhaps lay off some of the soiled clothing used in every-day work. But let us not think of making them happy by going to the other extreme and sending them into town to live, with nothing to do but to kill time. Oh, dear! what an expression—killing time—throwing away as valueless one of the most precious gifts that God ever gave!

I often find happiness by a change of occupation. Sometimes I take a day or two off, and, instead of going around among the clerks and hunting up things that are wrong, I go off in the country to ride my wheel, and in this way I find recreation, relief from care, and enjoyment; and, while I think of it, may be the dear friends at home find a certain kind of *relief* also. But I rather think they like to see me around, notwithstanding, especially when the Holy Spirit fills my heart, and these bright texts are bubbling forth and shining forth from my every-day life. But, again, how shall we all have a real happy New Year? Will lots of money bring it? Oh! no, no. Will a chance to ride in the Pullman cars, and plenty of money to

procure the best seat in the stage-coach, or to drive a stylish rig of one's own? Again, no, no. Will expensive clothing that will make people stare and wonder? Will a suit that costs enough to buy a farm, worn around every day, make you joyous and full of good nature? Surely not. It may be well for us, under certain circumstances, to wear our best clothing, and to look neat and tidy, and to be well dressed. We expect the pastor of our church to wear good clothes, and to keep them clean. His appearance is expected to be somewhat a symbol of his holy office; but where any individual expects by his fine and expensive clothing to let people see how much money he has, or have them take notice that he does not have to work for a living, or to let his clothes indicate in any way that he thinks himself of more consequence than people at large, then we certainly need not envy him, for I am quite sure he is not having a happy New Year. A good many times he is really to be pitied. So is the man to be pitied who, through pride or any other mistaken idea, burdens himself with that which does not benefit his fellows, or make him happy. There is no pure, lasting, substantial happiness to be found in this world except that which comes from helping to make others happy; and this is the secret of the Christian's joy and peace.

There is always a tendency among humanity to think that getting a great lot of this world's goods makes one happy. Children, at a very early age, exhibit selfish traits. They get a taste of delicious fruits, and straightway the little one, who has not got far enough along to know better, reaches out his hand to grasp and control *all* of the good fruit. When he takes a look at his brother or neighbor's child, and considers that the little companion loves these things too, a struggle commences in the little heart. Shall he divide? or shall he, because of superior strength, or because he has *possession*, monopolize the whole of it? Sometimes you can see the struggle going on in the little heart. It is a conflict between self and the higher and better trait of benevolence and love toward one's fellow-men. Oh, dear me! if it were only in childhood that we see this disposition, what a grand thing it would be! Who has not read of the exposures being made in the Tammany Ring business, without wondering how it is that men can be so foolish or so *behind the times* as to want, besides a liberal salary, large bribes of money, or gifts that may be offered them as a reward for violating a sacred promise, or for violating and trampling down the best instincts that can enter into the human soul? Surely there can be no "good things"—that is, *real, substantial* good things—in the life of a man who recognizes at every minute that he is traitor to his employer or traitor to the government which he serves. I wonder if they ever find professing Christians in such disgraceful work as this. What a *dead* kind of Christianity it must be, to find a man who professes to love God and his fellow-men *selling his soul* for the privilege of enriching himself just a little with something that does not belong to him! There are complications in business, I know, dear friends; there are places where it seems hard to decide what is exactly right and what is wrong.

But may God be praised, there is always open a way before us, or before any one who wants to do right. Make the matter a subject of prayer; ask God to tell you what is right and what is wrong. If you are honest and sincere in this you certainly can never go a great way astray. Our walk in life may be a very humble one. We may have to work very hard, and we may be obliged to wear poor and cheap

clothing; but we may enjoy to the fullest a host of good things—good things that rich millionaires have no suspicion of.

By the way, as the years roll on I am getting better and better acquainted with the men sent out by the different States to teach at our farmers' institutes. I have been greatly pleased to see how plainly and simply these teachers furnished by the State are dressed. They get pretty good pay; and if these men saw fit they might dress in much finer clothing than the average farmer, even when he comes to a farmers' institute. They are nice-looking men, every one of them; but I never saw any thing flashy or dudish about a single one of them. Almost if not quite all of the institute workers are Christian men. They quote quite largely from the Bible in their teachings and instructions. T. B. Terry often speaks Sunday evening, and his talks are very *practical sermons*, even if they do not contain very much theology. W. I. Chamberlain, the originator of the whole idea of farmers' institutes, is an ordained minister. Waldo F. Brown, whom I met only last week, at Ada, O., gave us one talk that I wish could be given from every pulpit in our land. It might include a good many practical every-day matters for a Sunday *sermon*, but I do not think it would be of any less value on that account. By the way, I have sometimes wondered who is back of our farmers' institutes. Who is it that decides in regard to the men who are *safe* and those who might be *unsafe*? Evidently, somebody who thinks our farming people do not need any more teachings in the line of skepticism. By the way, is it not true that progress in agriculture goes hand in hand with faith in God and belief in immortality?

The man who labors only for self, and for the enjoyment that he can find in selfish pleasures while his life shall last, and no further, can not well be a *progressive* man. He can not well be a help to the community in which he lives. He can not well be a blessing to humanity round about him. One who builds, however, for the benefit of generations who shall come *after him* must have faith in God. It seems to me, too, he must have an animation and inspiration that come only through faith in God, belief in a hereafter, and love toward his fellow-men. The man who does great things is the one who rejoices to see things going on, and to see people happy, even though he has no part in it. To go still further, the real hero whom we all love and reverence and respect is the one who is willing to bear *toil* and *pain* that *others* may be happy, and grow, and arrive at achievements that were unknown to him. This is the Christlike spirit. The lowly Nazarine *died* that we might *live*; and when we so far forget self that we are rejoicing and feeling happy to see others happy, and to see them grow in wisdom's ways, then shall we all at once discover we are getting hold of the *good things* ourselves. We are slowly discovering the *pearl of great price*. Let us now close with that beautiful thought given by Christ himself:

Then shall the King say unto them on his right hand, Come, ye blessed of my Father, inherit the kingdom prepared for you from the foundation of the world. For I was a hungered, and ye gave me meat; I was thirsty, and ye gave me drink; I was a stranger, and ye took me in. Then shall the righteous answer him, saying, Lord, when saw we thee a hungered, and fed thee? or thirsty, and gave thee drink? Or when saw we thee sick, or in prison, and came unto thee? Then shall the King answer and say unto them, Verily, I say unto you, inasmuch as ye have done it unto one of the least of these my brethren, ye have done it unto me.

SPACING STRAWBERRIES, ETC.

I have once or twice mentioned the difficulty of getting strawberries for field culture evenly spaced over the ground without having it cost more for labor than we could afford to pay. Let us go over the matter briefly.

Our strawberry-book directs that the rows be 4 feet apart, and the plants 2 feet apart in the row. This is the plan Terry has decided on, and he gets his fine even stands by letting the runners go out and set pretty much their own way; then in the fall he goes over the plot and takes out the superfluous small plants so none are left nearer than about 6 inches apart. I believe he assists in getting a complete matted row by spacing the runners while they are beginning to root—that is, he assists nature by placing the runners so as to cover the ground evenly. When it comes time to put on the mulch, the matted row is from 18 inches to 2 feet wide; and none of the plants, as I have before mentioned, are nearer than 6 inches apart. Well, a great part of our planting is done, as you know, in the early fall, after some crop is taken from the ground; and while our fall-set plants put out runners to a considerable extent, they do not, of course, produce so full a stand as where they are planted in the spring; therefore it becomes *exceedingly* desirable to have the new plants evenly spaced. In fact, we get finer and larger berries, because our plants have more room. But it is *exceedingly desirable*, as I have said, to have what plants there are, pretty thoroughly distributed over the ground—that is, over this strip of ground, say 18 inches wide and the length of the field. Now, I have for years been trying to find a man or boy who would do this spacing, and do it well. I hope none of our friends will feel hurt when I say that I have been again and again disappointed. I have said to myself, "Now, I am sure this man or boy will understand, with sufficient explanation, just what is wanted, and that he will fall in love with the job, just as I love it." In fact, I do not know of any prettier work in the world than to take a nice piece of ground, with strong thrifty plants putting out runners rapidly, and train them so as to have a nice even beautiful strawberry-bed. You think the matter is very simple, do you? Well, let me explain some of the points that the workman must keep constantly in mind:

First, he must swing the runners around to the right or left, so that the new plants shall not all be on one side of the old plant, at the same time keeping in mind that each new plant shall be at least 6 inches from its neighbor.

Secondly, as we keep the cultivator constantly running between the rows, the first thing to do is to make a narrow row—that is, avoid stretching a runner out at right angles so it will run out where the cultivator will be sure to dig it up. Of course, the man who runs the cultivator can swing around a plant thus stuck straight out, or he can jump his cultivator over it; but I emphatically object to putting him to this trouble. His business is to stir over every inch of ground possible, with the cultivator; and the man who sets the plants must bear this in mind and keep his row narrow—that is, he must *gradually* widen the bed out to 18 inches or 2 feet. Of course, some very thrifty plants will make the row a little wider at some points than it is at others; but it can be gradually

widened as the growth of any part of the bed demands.

Thirdly, the one who spaces the runners should keep constantly in mind that he is to fill up vacancies. If one of the original plants should die, by stretching runners straight out toward the spot it occupied, from each side, the vacancy can very soon be filled up; and during a favorable time, say just after a rain, some of the oldest and best-rooted plants can be taken up with a trowel, and moved to a part of the row where more plants are greatly needed. Now, this is not a difficult matter, neither does it require a great amount of labor, to have a nice stand of plants at no place being greatly crowded, and at no place having very many vacancies. I said I had tried a great many men and boys. I have not tried a smart *woman* yet; but if I don't have better success, I believe I shall try it. The trouble is this: Almost everybody I set at it gets along too fast. He says the strawberries are all done. I go out and look at a row; but before I have gone a rod I will find plants taking root not two inches from each other. I will find altogether too many plants at one side of the old plant, and too few, or none at all, on the other side. Then there will be runners sending out their white roots that have not been put in the ground at all; a good many plants right out in the path of the cultivator, when there was *plenty* of room to place them either at the right or the left—at least, very much *more* out of the way than where I find them. I suspect the trouble is this: The one who does the work is not particularly interested in the strawberry business, and his mind is on something else. Dear friends, it is next to impossible to do any sort of work well and thoroughly unless the work in question occupies all your thoughts, all your time, and all your attention. After the above prelude I have something to tell you.

Last week I had a splendid wheelride right in the month of January. I was attending a farmers' institute at Ada, Hardin Co., Ohio. While there I got acquainted with Henry Young, the originator of the Enhance strawberry. It is now one of the prominent strawberries before the people. It is a perfect berry, very prolific, beautiful in color, a strong grower, free from rust, and, in short, would be a model berry were it not for its awkward shape, and that some object to its tartness. This latter quality, however, makes it especially desirable for canning. The shape, however, has with many rather thrown it into the background, although the berries are about as large as any of the newer sorts. Well, I was greatly pleased to see friend Young's plantation, even in the month of January. This Enhance strawberry is his pet—his child. He loves it; and, as a consequence, it does wonderful things under the training of his loving hands. He too has met the same problem I have figured above, and he has solved it—at least, he has invented a way by which even a stupid man, or

FIG. 1.—MARKING OUT THE GROUND.

Please notice, the simplest and most accurate way of marking the ground will probably be to mark your whole field, marks 18 in. apart each way—that is, mark it lengthwise and then crosswise. Now commence setting your rows lengthwise of the lot. Set two rows; skip one for a path; two more; skip one, and so on.

one with his mind a part of the time on something else, might set out a bed so as to give a perfect stand. He does it this way: He sets out his plants in double rows, and this is done by setting the plants 18 inches apart each way. Now, this double row is 3 feet from the next double row. Fig. 1 will show how he marks out his ground.

After the ground is marked as above, with any sort of marker, you are ready to put out your plants. The path for picking the berries or for running the cultivator is just a yard wide. The plants, after the plantation is put out, are 18 inches apart each way. Let me show you some stars standing just as the plants stand when they are growing nicely, before putting out any runners:

```

* * * * *
* * * * *
* * * * *

```

FIG. 2.—PLANTS AFTER THEY ARE SET OUT.

Now a word about cultivating. The broad spaces, or the paths a yard wide, of course can be cultivated without any trouble; and if you set your plants with a spade, on the plan given by Dan White, you can run the cultivator within an inch of the plants on each side, without injuring them. As the rows between the plants are only 18 inches wide, you will probably do them easiest with a wheel-hoe. Friend Young uses a wheel scuffle-hoe. With a horse trained to the business, and a cultivator that will shut up narrow, I have sometimes done quite a good job of cultivating where plants were 18 inches apart. Please notice, before the plants have put out any runners, you can, with the horse-cultivator and the hand-cultivator, go through them both ways, so as to cultivate close up to each plant on four sides. By this means an acre of plants can be kept almost perfectly clean with modern cultivators and nothing else. Not only this, we can break the crust after every rain so quickly and so easily that we can afford to keep the ground loose and mellow, banishing all weeds at the same time that we do the stirring; and there has never been any thing invented, and in my opinion there never will be, to get great crops of any sort of fruit like this mellow, soft loose soil. So far so good; but when the runners put out and begin to take root, what then? Here is what I learned of friend Young's invention: No plants are allowed to take root in the broad path 3 feet wide—that is, not the first season, any way; but when the runners are just right, and begin to take root, your man or boy is taken into the patch with a trowel, and told to set a good plant about half way between all the old plants and one in the center of the square. After he has done this he is to cut off all the others. Let us have another diagram to make this plain. We have placed the stars a little further apart, so you can see better what you are doing.

FIG. 3.—HOW TO PLACE THE RUNNERS.

The large stars represent the original plants, and the small ones the new plants at the end of the runners. This, you will notice, makes a matted row, with the bearing plants just 9 inches apart each way. This is a little further apart than what Terry directs; but with the

strong thrifty Enhance, the space is not any too great. Each square contains nine bearing plants; and each bearing plant should give a great cluster of immense berries. If your plantation is made either in the spring or fall, your first crop will be like cut Fig. 2; and it will be an easy matter, with the horse-cultivator in the three-foot path, to keep this matted row clean, for the plants stand like hills of corn, except that the hills are only 9 in. apart, and you can work them with a narrow hand-cultivator, or you can use a hoe. Then comes the question, How many crops shall we get from this beautiful plantation before plowing it up? Mr. Young thinks it pays to get two crops; and he sometimes gets three. If you work for a third crop, after the first crop is picked, clean out your bed thoroughly, then let the runners set where they choose. Just let the whole plantation grow up to a thick mat of vines, leaving a 2 or a 2½ foot path for the pickers. Through this path, of course, you keep the cultivator going. After you have secured the crop from this solid matted row, then turn strawberries, weeds, and every thing, all under, the very day you do the last picking. That is, you ought to do it the very day, if you are going to work up to the highest notch of high-pressure gardening.* Now, friend Young goes to work and plants strawberries again, because his whole ground is used constantly for strawberries exclusively, or almost so. Meantime, however, he is pretty well convinced that some other crop should be put on before planting again for strawberries; and, by the way, you can get a good crop of cabbages, wax beans, early sweet corn, and ever so many other things, after turning under your strawberries. You may remember that, last season, I got a splendid crop of Freeman potatoes after the strawberries were all picked.

THE TIMBRELL STRAWBERRY.

In a little sheet called *Specialties for 1895*, published by the introducer of the Timbrell strawberry, we clip the following:

The Timbrell is a strawberry that has surpassed all expectations, yet not half its merits have been told. Each mail brings to us the cheering news that those who have planted it the past season can not speak too highly of it. Never has a new fruit so quickly become such a general favorite, succeeding so well in every locality, and never has there been such a run for plants as on Timbrell. We could not by any means supply the demand last spring.

There is no berry in existence to-day that includes the same combination of merits attained in Timbrell. Indeed, we say without fear of contradiction that there are not six berries on the market that combine the good qualities possessed by Timbrell alone. Hence you get in Timbrell the same points that you would get in half a dozen of the best varieties of the day. We claim still more: There is no variety in existence that can compare with Timbrell in quality, healthiness, vigor, and large average size; and there is but one other that equals it in productiveness, though it is soft and of poor quality.

You will notice in the above that not a word

* Please notice, in fall planting the routine would be something like this: Use potted plants; in fact, this is the way friend Young always does, for he is a greenhouse man, and handles pots every day of his life. Use potted plants, and the next summer you will get part of a crop of immense-sized berries. After fruiting, place the runners as in Fig. 2, and the second summer you will get a full crop—all large fine berries. Gather your fruit; get out the weeds, then let the whole plantation have pretty much its own way. Run the cultivator, of course, and do as much hand weeding as you can afford to do, more or less; then the third summer you will have an immense crop of berries as before; but a great many of them will probably be small, because the beds are too much crowded. Pick as long as it pays to bother with them, then get them under the sod, and have your field clean and lovely once more.

is said in regard to the objection made by the Ohio Experiment Station; viz., the peculiar blotches of white when the berry is fully ripened. Of course, the originator does not have very much to say in regard to the *appearance* of the berry; but is it fair to give a new berry such a recommendation as the above, after the decision that has just come out from the Experiment Station? I really hope the plant *will* have all the *good* qualities claimed for it in the above. The introducer of any new fruit, who mentions all of its good qualities and entirely *omits* the objectionable, will certainly hurt himself in the end a good deal more than he will gain, even *should* he succeed in disposing of his stock of plants at a good figure; and the latter is to be doubted.

TOMATOES FROM THE SEED IN 26 DAYS.

Last April I mentioned purchasing a package of seed of F. B. Mills. These were given the same attention that we give our other tomatoes, but they were little if any earlier than those we have already in the market. If any of our readers have had a different experience, we should be glad to hear from them; but it strikes me that any seedsman who advertises extensively that he has a strain of tomatoes that has given ripe fruit in 26 days after planting, will do himself an injury that it will take him many years to get over.

CRIMSON CLOVER SOWN THE LAST OF SEPTEMBER.

Our stand at this date, about the middle of January, is almost perfect. On the creek-bottom ground the clover is as green as if it were spring, and not a plant has been disturbed, although we have had several freezes almost down to zero when the ground was bare. I confess it is a great surprise to me. But the roots, after the fall rains, went away down deep, and spread out through the soil. If it goes through until April like this, crimson clover will certainly be one of the greatest boons that has ever come to the cause of agriculture. Just think of it! if, after taking off a crop in the fall, we can sow clover and get a good stand to be cut or turned under in time for potatoes or corn the following spring, we shall be almost a year ahead. Reports seem to indicate that this clover started in the fall, and turned under in the spring, is almost if not quite as good as a crop of red clover that has had over a whole year to grow.

GREENHOUSES, HOT-BEDS, AND COLD-FRAMES FOR FLORIDA.

Friend Selser tells us they do not have any such thing down there; but he says, also, he saw two carloads of garden-seeds from Chicago, going to Florida to plant new stuff where the other was killed. Now look here: About Christmas time they were selling ripe tomatoes; but before the new year had dawned, every tomato-plant was killed, root and branch. Are these Florida folks going to plant tomato-seeds, and wait through the very best of the season for more plants to grow? Are there no reserved plants kept under glass, or even under cotton sheeting, to plant out in the fields, and to come into bearing in a few weeks, instead of waiting for the slow process of growing things from the seed itself? If so, then I think Florida is just where A. I. Root is wanted, and perhaps just *now* is the very time they need him most.

THE WEATHER BUREAU AND THE FLORIDA ORANGES, ETC.

I suppose most of our readers know, as a matter of course, of the millions of dollars' worth of oranges, fruits, and vegetables lost by the recent cold wave in Florida. The clerk of the Weather Bureau says that telegrams were sent

all over; cold-wave flags were up on Friday morning, Dec. 28, announcing the blizzard that came on the 29th. The telegrams and daily papers show that full warning was given of the approaching cold wave 24 hours in advance; but notwithstanding this, little or no provision was made for the coming storm. It really gives me pain to notice how indifferent and stupid many seem to be in making use of this wonderful invention of modern times. I often talk with people in regard to important business transactions; but when the weather question comes in, it really pains me to hear them say, again and again, that they have not even looked at the weather-signals floating almost above their heads. Worse than this, there is a sort of foolish skepticism in regard to the ability of the department to predict the weather. But few seem to know that we can now tell about an approaching cold wave or storm almost as well as we can predict the coming of a train that starts, say, from Chicago and will reach Cleveland or New York at a certain time. It is our business (as displymen for Medina) to keep a record every day of the weather-predictions and the actual weather as it turns out. In the month of December our clerk recorded only *two* noes. All the rest of the predictions, both in regard to the *weather* and the *temperature*, were "yes," "yes," from the beginning of the month to the end.

In a recent copy of the *Rural New-Yorker* the editor asks how much the Weather Bureau was worth to farmers. The only response I have noticed was something like this: A man said it was worth a good deal to him; because, when the signal said "storm," he always expected fair weather, and *vice versa*. Now, this might have been well enough for a joke, but it was an absolute falsehood; and I protest against such falsehoods having a place in a good paper. If the editor's sanctum is where he can get his eyes on the weather-signals as they are run up, he can, with a pencil and paper, verify the predictions himself. In a recent storm on the lakes, millions of money and hundreds of lives were saved because the sailing crafts all stayed in the harbor on account of the predictions of the Weather Bureau. One vessel decided to disregard the storm-signal, and was lost, crew and cargo. Now to go back to the oranges.

Had our good friends in Florida gone to work picking their fruit on Friday morning, they might have saved millions of dollars; and thousands of people who are now almost bankrupt might have been getting the big prices that oranges are bringing at the present time. I know what I am talking about, for a bee-keeping friend, Mr. W. A. Sesler, is with us here to-day, and he has been all over Florida purchasing fruit, both before the terrible freeze and after it, and he was right in the heart of the orange regions when the freeze came.

USING SEEDS ONE YEAR OLD, ETC.

I have said before, that there are a good many times when I would give more for old seed that gave me a good crop the preceding year, of just what I wanted, than for any thing I could buy in the way of new seed. The following, on a postal, illustrates the point:

Mr. Root:—Have you any of the Golden Self-blanching celery seed left over from last spring, of the lot that I got that I lb. from in my seed order of Feb. 23d? I should like to get some of the same stock and lot.

Dundee Lake, N. J., Dec. 14.

HERMAN HILLMAN.

As soon as we heard from him we told him how much we had left of that very same stock. Here is his reply:

Find inclosed a check for \$3 worth of that seed

you have left over from last year's supply. If there is more than my check might cover, send it along and send bill. Send by mail. I will send you quite an order next spring for seeds. I found them to be as you represented.

Dundee Lake, N. J., Dec. 20. HERMAN HILLMAN.

Perhaps I may as well say that we are now keeping a careful record of all the seed we purchase (especially *whom it came from*), and we try make to at least a small sowing of every thing ourselves. Then we watch carefully for reports from others. The fact that a certain kind of seed *germinates* all right is but a small part of it; for really no one can tell whether the seed is just what he wants until the crop is *matured*. Our experience is, that a very large part of the seeds used for market-gardening germinate almost as well the second year as the first. Beans and corn—especially the latter—are liable to germinate, of course, a smaller per cent; but I have tested peas, purposely kept four or five years, and found little or no difference in germination, and none in the maturing of the crop. This may not, however, always be the case. Our experiment stations have, however, I believe, made some experiments in this line. I should like to have the market-gardeners tell us the result of their trials of different seeds tried the second year, or even the third. Of course, you are well aware of the great advantage in having some seed that you have raised a crop from (and a crop to your liking) the previous year. It is most specially desirable with such a plant as celery, to be sure that the fault (such a fault as sending up a seed-stalk, etc.), is in the soil, weather, etc., and *not* the fault of the seed.

THE CHEAP ONION-SEED, ETC.

I bought a large lot last year in Iowa, at 63 cts. per lb., while most seedsmen asked 90 at wholesale. The seed at 63 cts. was every bit as good as any I could get, and everybody was pleased. I find I can not get any as cheap this year, however, and do not like to buy any seed in a promiscuous way. I got a bag of Wardell's kidney wax beans the past season that were about all green-podded, and a source of a good deal of disappointment and vexation. They tell me that the stock was short, and they had to buy some, and suppose some one deceived them.

Sanborn, N. Y., Dec. 10. CHR. WECKESSER.

THE PARKER EARLE STRAWBERRY—A GOOD REPORT FROM IT.

Mr. Root:—Those Parker Earle strawberry-plants I got of you a year ago last September have done finely. We got 50 quarts from the 100 plants you sent. They did not make any new plants the first fall.

I have a nice lot of plants this year. Michel's Early does not do any thing for me; but one mile from here, on different soil, it does nearly as well as the Crescent. I have five of those nine best kinds, and one better—a seedling that my brother started nearly eighteen years ago. He has never tried to introduce it.

Parkman, O., Dec. 31. F. P. CLARK.

Friend C., I am a little astonished at the above. I was getting somewhat out of conceit with the Parker Earle after the way it "tumbled" during such a severe drouth as we had last season; and I am surprised to hear you say that it made no plants. Perhaps this was the secret of your great yield from it. I know Peter Henderson talks about getting a quart from a single plant; but I do not believe that I ever in all my life had a pint per plant right through from a row of 100 plants. And I am glad of what you say in regard to Michel's Early. This shows how much difference there can be in localities only one mile apart. If you have got a seedling better than the nine selected by our Ex-

periment Station, perhaps you had better let us try it. But, oh dear! it makes my back ache to think of the numbers we *have* tried, and found to be no better if as good.

TOMATOES AND SWEET POTATOES.

The "Buckeye State" tomatoes beat any thing in size ever seen here, even the Ponderosa, and in quality the Ponderosa is not to be compared to it. The second picking was 22 tomatoes (no thinning or selecting); weighed 17 lbs. 12 oz. It seems to me you would take hold of the Bunch (or Vineless) sweet potato. We like them better than the ordinary varieties, and they don't run.

E. A. BOAL.

Hinchman, Berrien Co., Mich., Dec. 12.

Thanks for your report. We have sold the plants of the Vineless sweet potato for two years past; but our soil is so poorly adapted to sweet potatoes that we purchase most of those we sell, in Baltimore.

DIGGING POTATOES BEFORE THE VINES ARE MATURED, DEAD, OR DRIED UP.

There, now, A. I. Root, on page 31 you have given a good pointer on growing potato-plants, and I just want to tell how those potatoes turned out that you told me, when here last October, not to dig until the vines were dead. You see I had taken from thrifty plants 12 side-shoots, each having a few roots, and I planted them on the 3d of July. One plant died; the 11 gave 11 lbs. of potatoes; and the very hill that I was about to dig up when you stopped me gave 3 lbs. Now, then, who will raise the most side-shoot potatoes of the Craig seedling, in 1895?

G. J. YODER.

Garden City, Mo., Jan. 5.

THE NEW CRAIG SEEDLING POTATO.

As orders continue to come in, and the potato seems to be receiving much favor, I begin to be quite a little anxious about its outcome. You see friend Craig, myself, and one of his neighbors, are almost the only ones who have given it a trial. Oh, yes! here is this much from Wm. Henry Maule. I take it with a letter from friend Craig:

I received Maule's report the day I mailed you my last letter. He says: "Your potato is a good one, very similar to Vick's Maggy Murphy; table qualities good." The Maggy Murphy is not given in any catalog I have. I will try to get some, and test them this year along with mine; but I am sure mine will prove the best, on our soil at least. Mr. Maule does not give the yield of either variety.

Zimmer, O., Dec. 22.

GEO. E. CRAIG.

In my description there is one thing I forgot to mention. The boys dug the potatoes while I was away, as you know. When that heavy frost came so early they covered them with sheets and blankets; but the freeze was too severe, and it killed the potatoes notwithstanding. Well, now I should have waited until the vines were entirely dry before digging. Perhaps it would have made but little difference, however. At any rate, the quality of the potatoes was extra—I believe a little better than those received from friend Craig himself; but that may be only a notion. Well, one day when we were down near where they grew, my good German friend and helper, Ben, pointed to the fence and asked me if I had seen that potato-vine. The root was stuck in a crack in the top of a fence, perhaps higher than my head, while the top of the vines reached down to the ground, with great spreading branches. As quite a few have asked for a dollar's worth of these potatoes by mail, we have decided to send 4½ lbs. for \$1.00. I should like to make it 5 lbs., but we can not quite do it and get peck prices. I omitted to say that one pound by freight or express will be 15 cts; 4 lbs., 50 cts.

PATENTS

Careful attention given to the prosecution of business before the U. S. Patent Office. All business treated as *strictly confidential*. No charge made for services in prosecuting application, until the patent is allowed. Send for "INVENTOR'S GUIDE."

FRANKLIN H. HOUGH,

HURRAH FOR FLORIDA.

ON Tuesday evening, Jan. 15, Constance and myself expect to start for Florida. During the past year she has been working in the office as shorthand writer and typewriter; so I shall have somebody along to whom I can dictate my Notes of Travel. Of course, I do not expect her to follow me in all my raids on the wheel, etc.; but she will be ready to "take down" when I get around full of interesting talk to you about. A. I. R.

CATALOGS PRINTED AT THIS ESTABLISHMENT.

We have just finished A. T. Cook's seed catalog for 1895, and I think the job does credit both to friend Cook and ourselves. We have printed his catalogs for several years, but never so good a one as this. Inasmuch as I have watched the growth of friend Cook's seed business for almost twenty years, perhaps I feel more than a usual interest in it. If you wish to see a new catalog, address A. T. Cook, Hyde Park, N. Y.

A VALUABLE STRAWBERRY CATALOG.

I have been greatly pleased by reading clear through from beginning to end a little catalog by C. N. Flansburg, Leslie, Mich. One refreshing thing about this is, that Mr. C. tells us how nearly all the plants he advertises have behaved on his own grounds; and where they have faults he evidently is as ready to tell about those faults as he is of the good qualities. Now, a good many who advertise strawberry-plants have nothing in their catalog whatever from individual personal experience. Can't a good many of us gather a moral right here?

ELECTRICITY.

I do hope our people will give this periodical a generous support. It tells you exactly the truth in regard to what electricity is doing in the world today; and, more than all of that, it sifts truth from falsehood, and sounds timely warnings against the stupendous frauds that are being continually put upon the people in the way of electricity for curing human ailments. Still further, it exposes frauds along this line, that do not have a bit of electricity about them. The price is only \$1.00 a year. Address *Electricity*, 6 Park Place, New York.

HONEY MARKET.

Our supply of extracted honey is very low, and we should like to get track of some more of it, in 60-lb. cans, not too far away. If any of our readers have such to offer we shall be pleased to hear from them. We have also placed out on commission very nearly all of the alfalfa comb honey we have been offering the past few months. We have reserved a little, which we offer to those in want of choice comb honey, at 15c per lb., in 100-lb. lots or more.

NEW PRICES ON SEEDS, ALSIKE, ETC.

The seed market changes so much that we are forced frequently to make new prices on many of the staple seeds. The following table gives the prices as they will appear in our price list now going to press. How long we shall be able to hold these prices will depend on the market. Most of the prices, you will notice, are lower than last quoted. Bag to ship in always included.

Name.	Price—1-lb.	Pk.	½ Bu.	1 Bu.	2 Bu.
Alsike clover seed	16	\$2 10	\$4 10	\$8 00	\$15 80
White clover seed	30	4 00	7 60	15 00	29 80

SECOND-HAND FOUNDATION-MACHINES.

Since our notice of these a month ago we have sold half of them, and are negotiating with parties for some of those which remain. Three more machines discarded from our wax room are added to the list. Those unsold at the present time are as follows:

Six-inch hex., No. 1461. Price \$10.00. This is in good condition, and just right for thin surplus foundation.

Six-inch hex., No. 1631. Price \$10.00. In good condition, and will make thin surplus foundation 10 ft. to lb.

Six-inch hex., No. 1565. Price \$12.00. This is in good condition, with very light wall, and will make extra thin foundation about 11 ft. to lb.

Six-inch hex., No. 1669. Price \$10.00. This has made a good many hundred pounds of thin surplus foundation in our wax-room, and will still do good work; has a few slight blemishes which are no detriment practically, but hardly suitable for the high standard of excellence attained by our foundation.

Ten-inch hex., No. 1640. Price \$12.00. This has been used for light brood, and is discarded for same reason as above; is an excellent mill otherwise.

Ten-inch hex., No. 1638. Price \$7.00. This is a new machine, and all right, except for one thing: The sheets do not come from the rolls easily, and it is therefore a source of some annoyance to use it.

Ten-inch round cell, No. G. G. Price \$6.00. This is old-style heavy cell wall, and makes foundation something like that from the Given press.

Ten-inch round cell, No. I. I. Price \$8.00. Similar to No. G. G.

All the above machines are our own make. We have also the following:

Hex. Vandervort, 10½-inch, No. H. H. Price \$8.00. Will do well for heavy brood.

Samples from any of above mills sent on application to those interested.

TRIUMPH MEAT-CUTTER.

Family meat-cutters are a very great convenience, and well nigh a necessity. Certain it is, that, if properly used, they will pay for themselves in a very little time in any family of ordinary size. There is hardly another item in the list of provisions for the family board that counts up faster than the meat-bill; and any thing that will serve to economize in the meat supply, and at the same time render much of it more edible, is certainly worth investigating. The Triumph meat-cutter, which we offer, is different from most of the old-style choppers, as will be seen from the illustration. It is also very easily taken apart to clean. We can furnish the Triumph for \$1.50 each. Special prices in quantities to agents.

CONVENTION NOTICES.

The annual meeting of the Ontario Co. Bee-keepers' Association will be held in Canandaigua, N. Y., Jan. 23, 26, 1895. Come early, every one. RUTH E. TAYLOR, Sec., Bellona, N. Y.

The 11th annual meeting of the Wisconsin Bee-keepers' Association will be held in the Capitol, Madison, Feb. 6 and 7, during the convention week of the State Agricultural Society, thus securing reduced railroad fare. Let all interested attend. Programs sent to as many as possible, but come whether you get one or not. H. LATHROP, Sec., Browntown, Wis.

The California State Bee-keepers' Association will hold its fourth annual meeting on Tuesday and Wednesday, Feb. 5 and 6, at the Chamber of Commerce, in Los Angeles, corner Broadway and Fourth Sts. Programs ready. J. H. MARTIN, Sec., Bloomington, Cal.

CATAWBA, S. C.

Revised Price List of Garden Seeds for Jan. 15.

Please notice that any or all seeds mentioned below are sold in five-cent packages, postpaid by mail. For 10 papers ordered at one time, 40 cts.; 100 papers, \$3.50. Of course, scarce and high-priced seed will necessitate making only a very small amount of seed in a package; but by far the greater part of them contain a full half-ounce of good fresh seeds. By comparing these packages with those you get of many of the seedsmen you will notice the liberal amounts we furnish for only 5 cts. It is true, we do not give presents or cash prizes; but we believe the most intelligent people of the present day would prefer to have their money's worth of what they ordered, rather than to compete for a prize. The five-cent packages are sent postpaid; but the price of all other seeds does not include postage; therefore, when you order seed by the ounce or pound, allow postage thus: 9 cts. per lb.; 5 cts. per $\frac{1}{2}$ lb., or 1 ct. per oz. Peas and beans by the pint and quart must also have 8 cts. per pint or 15 cts. per quart; for corn, add 12 cts. per quart for postage. Postage to Canada is double the above rates. One-fourth ounce, pound, or peck, will be sold at ounce, pound, or peck rates unless otherwise specified. In the enumeration below, no description of the seeds is given, as you may notice. Our complete catalog, with full description, will be mailed on application if you have not already received it.

ASPARAGUS.

Asparagus, Palmetto. Oz. 5c; lb. 50c.

Asparagus Roots. 2 year old. Palmetto, 10 for 10c; 75c per 100; \$6.00 per 1000. 2-year-old roots not available. 1 year roots, 10, 10c; 100, 50c; 1000, \$4. By mail, add 5c for 10; 25c for 100.

BUSH BEANS.

Henderson's New Bush Lima Bean. $\frac{1}{2}$ pt. 10c; qt., 30c; peck, \$1.75; bushel, \$6.50.

Kumler's Bush Lima. Qt. 40c; pk. \$2.50.

Burpee's Bush Lima. Pt. 25c; qt. 40c; pk. \$2.50.

Kidney Wax. Pt. 15c; pk. \$1.30.

White Kidney, Large. Pt. 10c; pk. \$1.10. Bu., \$4.00.

York State Marrow. The best field bean. Pint, 10c; peck, \$1.00; bush, \$3.50.

POLE BEANS.

Extra-Early Lima Beans. Price, $\frac{1}{2}$ pt., 10c; qt. 30c; peck \$2.00.

King of the Garden Lima. $\frac{1}{2}$ pt. 10c; qt. 30c; peck, \$2.00.

All of our beans will be furnished in 5-cent packages; but where they are to go by mail, postpaid, of course the above packages will have to be quite small. If wanted by mail, add 8c per pt. or 15c per qt. for postage.

BEETS.

Eclipse. Oz. 5c; lb. 40c; 5 lbs. \$1.50.

Laue's Improved Sugar. Oz. 5c; lb. 25c; 5 lbs. \$1.00.

Long Red Mangel. Oz. 5c; lb. 25c; 5 lbs. \$1.00.

CABBAGE.

Select, Very Early Jersey Wakefield. Stock seed. Oz. 20c; lb. \$2.50.

Henderson's Early Summer. Oz. 20c; lb. \$2.00.

Pottler's Brunswick. Oz. 15c; lb. \$1.75.

Excelsior Flat Dutch. Oz. 15c; lb. \$1.50.

Perfection Drumhead Savoy. Oz. 15c; lb. \$1.50.

Large Red Drumhead. Oz. 15c; lb. \$2.00.

CARROTS.

Early French Forcing. Oz. 5c; lb. 60c.

Orange Danvers, Half-Long. Oz. 5c; lb. 60c.

CAULIFLOWER.

Henderson's Early Snowball. Raised by H. A. March. $\frac{1}{2}$ oz. 25c; $\frac{1}{4}$ oz. 40c; oz. \$1.50.

CELERY.

Henderson's White Plume. Oz., 20c; lb., \$2.00.

Golden Self-Blanching Celery. Oz., 20c; lb., \$2.50.

New Rose. Oz. 20c; lb. \$2.00.

Dwarf Golden Heart. Oz. 15c; lb. \$1.75.

CORN (FOR TABLE USE).

Corn we sell at 5c per half-pint package; but at this price purchasers must pay the postage, which is 3c for each half-pint. If wanted in larger quantities the price will be 15c per quart, 75c per peck, or \$2.75 per bushel.

Cory's Extra Early.

Ford's Early Sweet.

Late Mammoth Sugar.

Country Gentleman, or Improved Shoepeg.

CORN SALAD.

Oz. 5c; lb. 50c.

CRESS.

Extra Curled, or Pepper Grass. Oz. 5c; lb. 40c.
Water Cress, true. Oz. 30c; lb. \$3.50.

CUCUMBER.

Early Frame. Oz. 5c; lb. 50c.

Improved Early White Spine, or Arlington. Oz. 5c; lb. 50c.

Green Prolific, or Boston Pickle. Oz. 5c; lb. 50.

LETTUCE.

Grand Rapids Lettuce. Oz. 15c; pound, \$1.75; 5 lbs. \$7.50. *This seed is from the originator, Eugene Davis.*

Boston Market (or White-seeded Tennis-ball). Oz., 10c; lb., \$1.00.

Henderson's New York. Oz. 10c; lb. \$1.00.

MELONS, MUSK.

Casaba, or Persian Muskmelon. Oz. 5 cts.; lb. 60c.

Extra Early Citron. Oz. 5c; lb. 60 c.

Banana. Oz. 5c; lb. 60c.

Emerald Gem. Oz. 10c; lb. 65c.

Miller's Cream, or Osage. Oz. 10c; lb. 60c.

MELONS, WATER.

Phinney's Early. Oz. 5c; lb. 40c.

Landreth's Boss. Oz. 5c; lb. 40.

MUSHROOM SPAWN.

Agaricus Campestris. Single lb., 15 cts.; 5 or more lbs., 12 cts. per lb., 10 lbs. or more, 10 cts. Directions for raising mushrooms sent with each order.

ONION.

Yellow Globe Danvers. Oz. 10c; lb. \$1.00; 5

Large Red Wethersfield. The standard red onion. Same prices as above.

PARSNIP.

Improved Guernsey. Oz. 5c; lb. 25c; 10 lbs., \$2.00.

PARSLEY.

Fine Curled or Double. Oz. 5c; lb. 50c.

PEAS.

Alaska. $\frac{1}{2}$ pt., 5c; peck, \$1.00; bush., \$3.75.

American Wonder. $\frac{1}{2}$ pt. 8c; pk. \$1.60; bu. 5.00
Premium Gem. $\frac{1}{2}$ pt. 5c; peck, \$1.00.
Stratagem. $\frac{1}{2}$ pt. 8c; qt. 25c; pk. \$1.50; bu. \$5.
Champion of England. Pint, 10c; pk. 75c; bushel, \$2.50.
Peas by mail will be at same rate as beans for postage.

PEPPERS.

Sweet Spanish. $\frac{1}{4}$ oz. 8c; oz. 20c.
Bullnose. $\frac{1}{4}$ oz. 5c; oz. 15c.
Cayenne. $\frac{1}{4}$ oz. 8c; oz. 20c.

POTATOES.

Monroe Seedling.
 1 lb., by mail, 18c postpaid; 3 lbs., 40c; by freight or express with other goods, 1 lb., 5c; 1 pk., 35c; 1 bush. \$1.00; per barrel of 11 pecks, \$2.50.

Early Ohio.
Everett's Early, 6 weeks.

Early Puritan.
Lee's Favorite.
Rural New Yorker.
Freeman.

Prices of any of the above: 1 lb., by mail, 20 cts.; 3 lbs., 50 cts.; 1 lb., by express or freight, 10 cts.; 1 peck, by express or freight, 50 cts.; 1 bush., \$1.50. Barrel, containing 11 pecks, \$3.50. If potatoes are ordered in the winter we will do our best to protect them from frost, but the purchaser must take all risk. At these prices we make no charge for burlers or packages, but deliver F. O. B. cars here in Medina. Second size, until sold out, one half above prices.

SECOND-SIZED Freemans, while they last, same price as Monroe Seedlings. Our second size this season were raised by T. B. Terry.

Potato-eyes. Any of the above varieties by mail postpaid, 15c for 10; or 80c per 100.

The New Potato, Craig Seedling.

A full description containing all we know in regard to this new potato, will be found in our issue of Dec. 15, commencing on page 939; see also page 929, in the same issue. Prices will be found on this page, just below; and if you have not a December number handy, the whole history of the potato, so far as we have it will be mailed you free on application. We think at least every potato-grower who is interested in a new large potato of most astonishing vigor, and freedom from scab, blight, or any thing of the kind, should test at least a single pound, which will be sent postpaid, for only 25 cts. We shall be glad to furnish you further particulars.

The A. I. ROOT CO., Medina, Ohio.

PUMPKIN.
Early Sugar. Oz. 5c; lb. 40c.

RHUBARB.

Myatt's Victoria. Oz., 10c; lb., \$1.00.

Breadstone. Oz. 10c; lb. 50c.
White Egg. Oz. 5c; lb. 40c.

The New Craig Seedling Potato.

For full description of this Potato, see page 959 of this journal for Dec. 15, 1894. Prices: 1 lb. by mail, postpaid, 25 cts.; $\frac{1}{2}$ peck, by freight or express, \$1.00; peck, \$1.75; $\frac{1}{4}$ bushel, \$3.00; bushel, \$5.00; barrel of 11 pecks, \$12.50. The above prices will hold good as long as our stock lasts. All orders by mail will be filled as soon as received. Orders by express will be shipped at once unless ordered otherwise. All orders for potatoes by freight will be filled April 1, or soon after that time, unless directions are given to ship at an earlier date. In this latter case I do not assume responsibility for loss in freezing; but where it is desirable to ship earlier, and customers have bad luck, I expect to help them out so far as I can consistently. In regard to my responsibility I would refer you to A. I. Root. In fact, where it is more convenient you can order potatoes of the A. I. Root Co., instead of sending your orders to me.

 W. Atlee Burpee & Co., Philadelphia, Pa.

Maple-Sugar Supplies.

The time is at hand when those who produce the delicious sweets from the sugar maple must be getting ready. For the best results you must have good clean apparatus of the most approved type, and you really can not afford not to read Prof. Cook's book, "Maple Sugar and the Sugar-bush," which we furnish at 35c. or we will give a copy free to all those who buy sugar-makers' supplies of us to the amount of \$10.00 or more. We do not sell evaporators, but we think we can do you some good on spouts, pails, covers, and cans. We have received a carload of these from the factory, and they are made of American tin-plate. The plates are tinned and made up into cans by the same firm; and by taking a carload we get them at bottom prices. See table below. The pails and cans are machine-made, far superior to hand-made, and guaranteed not to leak.

BUCKET WITH HINGED TIN COVER.

This cut shows the manner of hanging the bucket on the spout, and also the manner of emptying with the hinged tin cover. Most progressive sugar-makers nowadays use covers of some kind.

PRICE LIST OF SAP-PAILS, COVERS, CANS, ETC.

Record sap-spout, \$1.00 per 100.....	\$8.00 per 1000			
1-gal. square cans, \$10.00 per 100.....	\$90.00 "	100 "		
1 gal. square cans, 6 in a box, 85c. per box; \$8.00 for 10 boxes.				
1-gal. square cans, 10 in a box, \$1.30 per box....	\$12.00		for 10 boxes.	
5-gal. square cans, not boxed, 28c. each.....	\$5.00		for 20 cans.	
5-gal. square cans, 2 in a box, 70c. per box.....	\$6.50		for 10 boxes.	
5-gal. square can, 1 in a box, 45c. per box.....	\$4.00 for 10 boxes.			
Grade of tin.	Price per 100.	10 qt.	12-qt.	15-qt.
IC charcoal or bright tin				
sap-buckets, \$14.00	\$15.00	\$17.50		
IX charcoal or bright tin				
sap buckets, \$16.00	\$17.00	\$20.00		
Heavy galvanized sap-buckets.....	19 00	22 00		
IC coke-tin sap-pails.....	13 00	15 50		
IX	15 00	18 00		
Hinged tin covers.....	6 00	per 100		
Reversible wood covers, painted..	4 50	"	100	

The sap-pails in above table, of coke tin, are offered to compete with other cheap buckets you will find in the market. The best are the cheapest in the long run. The tin in these cheap pails is just the same as in the better ones, except the coating, which is much thinner. We guarantee these equal or superior to the other cheap buckets in the market, but, recommend, instead, the higher-priced ones with better coating. The galvanized iron pails are coated after they are put together, and will never rust out. It requires more care to keep them clean.

THE A. I. ROOT CO., MEDINA, O.

KIND WORDS FROM OUR CUSTOMERS.

The hives and sections are beautifully made, and I am very much pleased. JOE L. COOPER.
Nashville, Tenn., Nov. 20.

The sewing-machine I ordered of you Nov. 26 was received Dec. 24 in good condition. It is a daisy, and my wife is more than pleased with it. LEWIS DAMON.
Fitchburg, Mass., Jan. 7.

OUR POTATO BOOK.

Mr. T. B. Terry:—
I consider your book one of the greatest works on agriculture that I ever read. It needs a new title, however. Instead of the "A B C" of Potato Culture it should be called the "A to Z."

W. A. LINN,

Managing Editor *Evening Post*.

New York, Dec. 20.

THE COWAN EXTRACTOR, AND HOW ESTEEMED BY A CUBAN.

I received a few days ago a Cowan extractor, No. 25, through Messrs. Falconer, bearing your imprint. I am glad to express the satisfaction which I feel in regard to the machine, which, perhaps, is the best now in use by bee-keepers. I have promised myself to use nothing but the Cowan in the future.

JOAQUIN CASQUERO BARREDO.

Cardenas Cantel, Cuba.

BEEES AND BIBLE.

By chance I came across some old back numbers of GLEANINGS, which I readily devoured, and, like "Poco," greatly desired more. I consider GLEANINGS superior to any other bee-book, and your Home chats very instructive and entertaining. I think you missed your calling. You thought the Lord said *bees*, and he said *Bible*. I have half a dozen stands of bees; am an enthusiast on the subject, though I am without knowledge or experience in regard to them.

MRS. CARRIE M. ROBERTSON.

Mayview, Mo., Jan. 8.

A KIND WORD FROM A "STRAWBERRY-CRANK," ETC.

Mr. Root:—I am pleased to see what perhaps is an outline of your face. You have been at times the only man talked about in my house. My son, at one time, was a bee-crank, purchased the A B C book, and took your journal; but I have the book, also your "Tomato" and "Strawberry" book. Of course, other names are in the book, but I can see A. I. Root in it all. I am in the middle sixties, and have never drank spirits, nor smoked or chewed tobacco; am a strawberry crank, and wish to learn the name of the berry coming nearest to the following description: Fair or good size; dark-red flesh; red through and through; very firm, with flavor very fine, strong acid; of course fairly productive. I wish it for a canning berry. Will you tell me the berry? It will be a great point to gain. I contracted the strawberry symptoms about two years since; have now about six acres under cultivation. I raise the Gandy for market. It would be a fine canning berry if it had dark-red flesh, and was not a little bitter when canned. If you know all about the old Champion, or Windsor, as it is now called, please tell me if it has fine flavor or not. D. F. BROWNS.

Freeport, N. Y., Dec. 31.

Friend B., my impression is that the Warfield comes nearer your description than any other berry we have. The strawberry-growers who read GLEANINGS can, however, correspond with you, if they choose.

In regard to the outline of my face, I am afraid the picture in the berry-book is hardly as much as an outline. If it were not that it is a foolish thing to feel hurt because your picture does not do you justice, I do not know but I should have scolded some about this picture before this. The worst of it is, it shows a scar, or deformity, that does not exist at all. When I first saw it I thought that, perhaps, it was a blur in the printing; but other books show it just the same. Had Judge Biggle given me an opportunity, I would have furnished him a cut that would have made me look at least tolerably respectable in such a crowd of bright able men. Our stenographer suggests, that perhaps the rest feel something as I do; but it seems to me every one must admit that A. I. Root is the *sortiest*-looking chap in the whole crowd.

BOSTON.—*Honey.*—Our honey market remains about as it has been, with light demand. Comb honey, 14c; extracted, 5@6c. E. E. BLAKE & CO., Jan. 19. Boston, Mass.

KANSAS CITY.—*Honey.*—The stock of comb honey is large; market well supplied. Fancy white 1-lb. combs, 15; amber, 12@13. Receipts of extracted, light; white, 7; amber, 5½@6; southern, 4½@5. Beeswax, 22. HANBLIN & BEARSS, Kansas City, Mo. Jan. 19.

ST. LOUIS.—*Honey.*—There is some improvement in trade since our last report. We quote clover comb, 16; amber, 12½@14; extracted in cans, 5½@6; in barrels, 4@4½. Prime beeswax, 28. D. G. TUTT GROCER CO., St. Louis, Mo. Jan. 18.

CLEVELAND.—*Honey.*—Honey is slow sale. No. 1 white in combs at 14@15; No. 2 white, 12@13; No. 1 white extracted, in 60-lb. cans, 6@8. Beeswax, 25@27. WILLIAMS BROS., 80 & 82 Broadway, Cleveland, O. Jan. 17.

DETROIT.—*Honey.*—Supply of comb honey increased, and more than equals the demand. Prices remain the same. Best, 14@15; dark, 11@12; extracted, 6@7. Beeswax, 26@27. M. H. HUNT, Bell Branch, Mich. Jan. 18.

KANSAS CITY.—*Honey.*—The demand for comb honey is improving. No change in extracted. We quote 1-lb. comb, white, No. 1, 14@15; No. 2, 12@13; amber, No. 1, 13@14; No. 2, 10@11; extracted, 4½@6½. Beeswax, 22@25. C. C. CLEMENTS & CO., Kansas City, Mo. Jan. 19.

ALBANY.—*Honey.*—There has been quite a demand for both comb and extracted during the past few days, and our stock is considerably reduced. We quote white comb honey, 12@13; buckwheat and mixed, 9@10; extracted, 4½@6½. CHAS. McCULLOCH & CO., Albany, N. Y. Jan. 19.

DENVER.—*Honey.*—Our market seems rather on the decline, owing largely to the depression of the "times." We quote No. 1 white comb, put up in 24-lb. cases and suitable to put into cartons, 10@11; No. 2, in 24-lb. cases, 9c; No. 1 extracted, in 60-lb. cans, 6@6½; No. 2, in cans, 5@5½. The demand for extracted is quiet, with a good supply on the market. Choice yellow beeswax, 2c. R. K. & J. C. FRISBEE, Denver, Col. Jan. 22.

SAN FRANCISCO.—*Honey.*—White extracted honey, 6½@7; light amber extracted, 6c, probably 4½c; 1-lb. frame, 10@12. Beeswax scarce at 27c. SCHACHT, LEMCKE & STEINER, San Francisco, Cal. Jan. 24.

MILWAUKEE.—*Honey.*—The new year opens with a good supply of honey on hand, and rather a dragging trade. The late receipts are not of as good quality or condition as desired, and a want of care on the part of shippers plainly shown in not packing sections in cases in a neat and marketable manner, hence the honey is broken and not very attractive. We continue to quote best 1-lb. sections, 16@17; good, 14@15; common, 12@14; extracted, white, 6½@7½; dark, 5½@6. Beeswax, 23@25. A. V. BISHOP & CO., Milwaukee, Wis. Jan. 18.

SPRINGFIELD.—*Honey.*—White clover honey, 15@16; buckwheat, 12. Our market is not active; it is selling slowly. PERKINS & HATCH, Springfield, Mass. Jan. 17.

MINNEAPOLIS.—*Honey.*—Prices are low, and trade is demoralized. Fancy white comb, 16@17; No. 1 white, 14@15; fancy amber, 13@13½; No. 1 amber, 12@12½; fancy dark, 12; No. 1 dark, 10c; extracted, white, 7; amber, 6; dark, 4½. J. A. SHEA & CO., Minneapolis, Min. Jan. 22.

We yet have extracted alfalfa at \$7.80 per box of 120 lbs. AIKIN BROS., Loveland, Colo.

Closing out balance of my fine extracted basswood honey at 7c f. o. b. Who is not supplied? ELIAS FOX, Hillsboro, Wis.

ALFALFA HONEY. very white, thick, and rich. Two 60-lb. cans at 7c. Same, partly from cleome (tinted), 6c. Samples, 8c. OLIVER FOSTER, Las Animas, Col. eift

WANTED.—5000 lbs. clear yellow beeswax, at 27c cash; also several tons pure extracted honey that does not contain basswood or buckwheat; also several tons pure extracted white-clover honey, at 10c; send sample and quantity before shipping. WM. A. SELSER, 10 Vine St., Philadelphia, Pa.

FOR SALE.—Alfalfa comb honey, snow white, 12c; partly from Cleome, light amber, 11c. D. S. JENKINS, Las Animas, Col.

I told you so.

Mrs. Atchley:—The one-frame nucleus I got of you last spring gave me 120 well-filled one-pound sections. J. A. SMITH, Heber, Utah, Oct. 9, 1894.

Now, haven't I told you that it will pay to send bees north in the spring?

One-frame nucleus, \$1.00; 10 or more, 90c each. Bees by pound, same price. Untested queens to go with them, 75c each.

Untested queens by mail, \$1.00 each; \$5.00 for 6; \$9.00 per dozen, till June; after, 75c each; \$4.25 for 6, or \$8.00 per dozen. I breed the leather-colored Italians, 5 bands, and Carniolans, in separate yards, at safe distance.

Tested, 3 bands, \$1.50 each; 5 bands or Carniolans, \$2.50 each.

Fine breeders of either race, or imported queens, \$5.00 each. Full colonies with untested queens, \$6.00. Ask for discounts to dealers, and by quantities.

The only steam bee-hive factory in south Texas. Root's goods, Dadant's foundation, and Bingham smokers.

Safe arrival on every thing guaranteed. Send for FREE catalog that tells all about raising queens.

JENNIE ATCHLEY, Beeville, Bee Co., Texas.

WE have a large stock of **SECTIONS** now ready, both No. 1 and No. 2. Write for special prices on winter orders in large or small lots, including all other supplies. Also **Berry Crates and Baskets** made up or in flat.

Wants or Exchange Department.

Notices will be inserted under this head at one-half our usual rates. All advertisements intended for this department must not exceed five lines, and you must say you want your advt in this department, or we will not be responsible for errors. You can have the notice as many lines as you please, but all over five lines will cost you according to our regular rates. This department is intended only for bona fide exchanges. Exchanges for cash or for price lists, or notices offering articles for sale, can not be inserted under this head. For such our regular rates of 20 cts. a line will be charged, and they will be put with the regular advertisements. We can not be responsible for dissatisfaction arising from these "swaps."

WANTED.—To exchange one-piece-section machine, steel feed-grinder (½ ton per hour), 8 H. P. engine, 25 ft. 8-inch rubber belt, for brood fdn. or Hoffman frames with comb wired.

A. D. WOOD, Lansing, Mich.

WANTED.—Two or three hundred colonies of bees to run on shares for comb or extracted honey the coming season, or to take charge of as apiarist. Reference, W. L. Cogshall, West Groton, N. Y.

RUSSELL T. STINNETT, Bells, Va.

WANTED.—To exchange Cuthbert or Marlborough raspberry-plants for beeswax, honey, or offers.

C. G. MARSH, Belden, N. Y.

WANTED.—Offers on a new 200-egg Noxall incubator at \$15.

R. C. AIKIN, Loveland, Colo.

WANTED.—To exchange supplies and other goods for honey. O. H. Hyatt, Shenandoah, Iowa, 20tf

WANTED.—To exchange several good safety bicycles. Honey wanted. Send sample.

J. A. GREEN, Ottawa, Ill.

WANTED.—To exchange 200 colonies of bees for anything useful on plantation.

ANTHONY OPP, Helena, Ark.

WANTED.—For spring planting, apple, quince, currants, gooseberry, strawberry, in exchange for golden queens, in June.

J. F. MICHAEL, Greenville, O.

WANTED.—People to drop a card and tell me what they have to exchange for Gregg and Cuthbert raspberry and strawberry plants. No. 1 stock.

DAN WHITE, New London, O.

WANTED.—To exchange bee-supplies for either Gem or Cigar-box planer.

E. J. SHAY, Independence, W. Va.

WANTED.—To exchange dark extracted honey for a 20 or 30 inch cut-off buzz-saw; also foundation-mill, for offers.

F. W. STEVENS, Moore's Hill, Dearborn Co., Ind.

WANTED.—5 to 8 H. P. engine, in good repair, price and kind.

H. A. ALLEN, Milton, Vt.

WANTED.—To exchange a Simplex Hatcher and brooder combined, 160-egg, used two settings, price \$12.00, for 150 lbs. of good extracted honey.

J. VAN PETTEN, Linn, Kansas.

FOR OFFERS.—One No. 2 Automatic gauge lathe, and 1 improved gauge lathe (for handle-making). Let me know a good location for a custom sawmill, some one.

W. S. AMMON, Reading, Pa.

Over \$5.00

Is what it costs to take the leading bee-journals, even if secured at clubbing-rates. The BEE-KEEPERS'

REVIEW endeavors to give the CREAM of all these journals, and it costs only \$1.00. If you can't afford to take all of the journals, yet wish to be well informed in apicultural matters, try the REVIEW.

A YEAR'S WORK AT FORDHOOK FARM (BEAUTIFULLY ILLUSTRATED)

IN this new book just published the pen and camera transport its reader to "Fordhook," the Model Seed Farm of America—in so far as such a thing is possible—by affording him a comprehensive view of it as it actually appears. Although the price is 10 cents, we will, upon receipt of **two 2-cent stamps**, mail a copy to any planter who desires to read it before sending this season's order for seeds. Shall we mail you a copy now?

In addition to the many charming views of "Fordhook," it contains photographic illustrations of a unique Floral Wonder to appear in 1896—something absolutely without parallel in the annals of Horticulture. One dollar per seed would not buy a packet now; but we believe flower lovers the world over will be glad to learn, a year in advance, of the coming of the greatest novelty that has yet rewarded the scientific cultivation of flowers. 'Twill produce a profound sensation in '96, and it were wise for you to-day. Address,

W. ATLEE BURPEE & CO., Philadelphia, Pa.

A BRIGHT BOOK ABOUT SEEDS (JUST ISSUED)

Bright alike inside and outside. The outside is red, and the inside certainly will be—by all who need live seeds.

Mailed free to any address sent on a cent postal card. You'd better spend that cent to-day? ADDRESS AS ABOVE.

Early
Queens
By
Return
Mail.

Choice Tested Italians, vigorous and prolific, \$1.00 each.

These queens were reared in the fall of '94 for our early spring trade, and are guaranteed to give satisfaction.

FEB. 1, 1895.

No. 3.

STRAY STRAWS FROM DR. C. C. MILLER.

I JUST BELIEVE that C. Davenport has given a capital plan for mice, p. 54, to give them such a variety.

HONEY SOURING in the hive is something I think I never heard of till lately. How far north has it been known?

THAT STATEMENT on p. 45, that E. France has 140 colonies in the home yard, makes me all alive to know whether that's the regular thing, and what supports so many.

A BRIGHT AMERICAN girl was asked in England what was done with so much fruit in this country. She replied, "Oh! we eat what we can, and we can what we can't."

IS EUCALYPTUS, that Prof. Cook tells about, p. 52, the same as in Australia that Australians say is so fine, and that bee-keepers in England will not admit is fit for the table?

FROM SWITZERLAND come reports of two cases of fecundation of the queen during the act of swarming. I had supposed it was quite a common thing with after-swarms. How is it?

I'M GLAD TO KNOW that cement-coated nails are better than rusted. Sometimes I rust them purposely; but it's troublesome to do it well, and, besides, I don't like the looks of the rusty nailheads.

"ALWAYS make a new colony a full colony, especially if made late in the season," says E. France, p. 44, and it's worth saying again, both for the sake of getting that dash out, and emphasizing it for beginners.

ABOUT 150 COLONIES of live bees were at the great German convention and exposition, nearly all black or German bees. Somehow black bees have more friends in England and on the continent than in this country.

EDITOR LEAHY tells what a good time he had with J. T. Calvert, of the A. I. Root Co., at a visit on the way from St. Joe. Now, you can

fling all the mud you like at the "mutual-admiration" business, but that sort of talk makes a good bit nicer reading than mud-flinging.

A GOOD POINT in favor of laws against adulteration is given by S. E. Miller, in *Progressive*. It gives the public more confidence in purity of product. Lately, in a region where good cheese-factories abound in Illinois, I found New York cheese on the table, simply because New York laws were more strict as to pure cheese.

AFTER READING what E. France says, the old question comes back whether *covered* sealed covers may not be all right, and *uncovered* sealed covers all wrong. His covers have straw over them. Is there nothing but the sky over yours? [No, sir. There's a good big cushion and cover over them. Our sealed covers have always been so protected in winter.—ED.]

"FRUITS produced by self-pollination are quite different from those produced by cross-fertilization. Few varieties of apples will self-fertilize to any extent. The chief agents for fertilization are insects, and honey-bees are among the best. Every fruit-grower should keep some bees to fertilize his blossoms, or see that his neighbor does."—*Green's Fruit-grower*.

A SYMPOSIUM of six articles on five-banded bees occupies most of the *Progressive* for January, leaving the impression that there are five-banders and five-banders, or, as Hutchinson expresses it, "the dark, leather-colored bees are, as a rule, the better workers, but the brighter-colored bee *may* be just as good workers as their darker sisters . . . and *some* strains are." [Them's my sentiments, and I think they agree fairly with what I have said.—ED.]

"THE HONEY-BEE is not able to pierce the skin of fruits; but they have the power of getting in between the joints, as one might say, consequently they manage to work in between the pips of the raspberry, and also into the grape, near its junction, and in this way crops of grapes and raspberries are wholly ruined by bees." That's what Meehans' *Monthly* says. Now, will that good monthly tell us just how it found that out?

THAT WAX is secreted by bees, and not gathered somewhere outside the hives, was, according to Cowan, discovered as early as 1684 by Martin John, and soon after by Thorley; but no great notice seems to have been taken of it till it was rediscovered by a Lusatian peasant whose name, Cowan says, is, unfortunately, not given. Herr Beck, in Gravenhorst's *Bienenzeitung*, gives H. C. Horebostel as the name of this man to be remembered for his discovery in 1720.

THE DOCTRINE that each nurse-bee prepares food for larvæ of a particular age gets a black eye from Gravenhorst. He thinks it will not do to say that a bee 9 days old is too old to feed a larva one or two days old, because, when brood-rearing commences in spring there are none but old bees present. Also, after a colony has been long queenless in summer the larvæ are well fed on the introduction of a queen. Dzierzon, in Noerdlingen *Bienenzeitung*, pokes fun at the whole idea.

FOUL BROOD raged for two years in the apiary of Herr Fulde, in spite of all efforts at cure; then every two or three days a few drops of the new disinfectant, lysol, was given in the bees' food, and it worked like a charm, all traces of the disease disappearing for good in three weeks. Now, what's lysol? and will it work in the English language as well as in the German? [I should be interested also, in knowing whether the disease stayed away. Perhaps Herr Gravenhorst will answer these questions.—Ed.]

HERR REEFEN, the great German gleaner, sturdily opposes the idea that workers carry eggs or larvæ from one cell to another, and yet he has most faithfully given all the testimony favoring such belief. He now sums up as advocates, Langstroth, Wagner, Root, Abbott, Americans; Editors Bertrand, Wathélet, French; but Germans and English seem to be absent from the list. [I have personally seen a worker carry an egg (not larva), but what it did with it I can not be positive. I was not interested at the time, and so did not take the pains to follow the bee up.—Ed.]

YE EDITOR is a little too sweeping when he says, p. 23, that color will detract from both prolificness and the honey crop. Best qualities don't necessarily go with any shade of color. I like leather color, not because that color makes good bees, but because good bees happen to have that color. [The last sentence taken alone (and to which you doubtless refer) does sound a little strong; but when taken in connection with what precedes, and especially with what I have said aforetime on this same question, I don't think my meaning will be misunderstood. What I meant was that it was *liable*, under the present craze, to detract from both of the qualities—prolificness and honey-gathering, because, in the selection of the one thing, color, the other things are left out of the

consideration; or, rather, the undesirable traits are allowed to creep in.—Ed.]

GENERAL CORRESPONDENCE

CAMPING, FISHING, CUTTING BEE-TREES, ETC.

HOW TO GET BEES OUT OF TREES WITH FEW OR NO STINGS: A QUESTION FOR C. A. HATCH TO ANSWER.

By E. France.

I have been in the habit of going to the Mississippi River and camping out, or living in a tent, from four to eight weeks, for the last five years. I go for sport and health. I think it does me good, and it gives me rest from other labor. My wife has gone with me three years, and she stays about five or six weeks, then takes the train and comes home, and I stay two or three weeks longer. I usually stay until it gets pretty cold, as we get better fish after the weather gets cold enough to use an overcoat and mittens.

I have a partner, a Galena man, who camps with me and stays as long as I do. We each have a boat and a tent, a stove in the tents, good beds, and camp-outfit. We are as comfortable there as at home, with plenty of fresh air. We catch catfish, buffalo, bass, pike, and a few other kinds. We fish with rod and line. At that time of the year we catch mostly pike, called there salmon, but they are *not* salmon.

I was feeling pretty miserable—tired out, no appetite. After I had been there three days I thought I should have to give it up and go home. But I stayed; and after I had been there a week I got stronger, and got a "river appetite," as I call it. After that I was all right, and able to handle my boat without tiring me as it did at first. I went down the 20th of September, and came back the 12th of November; but as the weather turned out, the best fishing was after I came home. As for fish, I got enough. I salted a 15-gallon keg full, and sent home once a week a good market-basket full.

With the rest of the fun I helped to cut two bee-trees. I was down there, and stayed a week with Newel France and his whole family in August. I found those two bee-trees on an island. The island belonged to an old fisherman. He lived in a cabin on the island—the same island that we camped on later. I showed him the trees, and told him I would help him cut them when I came down in the fall to fish. So when I went in September I took along a smoker and brush-broom, and a paper of tobacco. You see I wanted a good strong smoke, as the trees had to be chopped down,

and the bees would get a terrible jar, and would be mad.

After we had been in camp about three weeks the old man came to our camp one day and said the boys had come to cut the bee-trees. The boys were the old man's sons, three of them, and all married. The old man said the boys were chopping down one of the trees. "That won't do," I said. "Go to them as soon as you can, and tell them not to fall the tree until I get there." It was very important that I should be there when the tree fell. He got to the tree in time to stop the chopping. got together what things I wanted—smoker, brush-broom, pail for honey, veil in my pocket, etc. One of our fishing partners went along to see me handle the bees, as he had cut a tree once, and got nearly stung to death.

When we got to the tree we found the boys waiting for us, with the tree still standing. I filled my smoker and lighted it; and as this tree had a good many large limbs it was not likely to fall hard, so I did not put on my veil. "All ready! let her drop!" A few licks with the ax, and down it came. Just as soon as I could get to the top of the tree I was there blowing my smoke into the entrance. Very few bees had got out, and what few there were out went up to where the top of the tree had been—out of our way.

The next thing to do was to get out the honey. "Come on, boys, with the ax." No reply. I went back to the stump. No one was in sight. I halloed; no answer. I took an ax and went back into the top of the tree, and smoked the bees a little more; then I got to work cutting away the brush, getting ready to open up the tree. Directly I heard the old man call from the brush, back beyond the stump. "Mine crashus, man, de pees eat you up."

"No," I said; "get the other ax and come here and help chop. The bees don't sting me, and they won't sting you."

"I'm nod so sure. I pe so 'fraid of dem pees."

"Never mind; come on; if they sting you when you get here I will chop them out."

He came and helped me get out the honey; But those brave boys of his never got nearer than the stump of the tree. My fishing partner came and helped some, after some coaxing. We got two large dishpans full of nice honey—not smashed up much. We swept the bees off the combs a piece at a time, and left them scattered all over the ground. I never saw them after. The old man said the bees after that gathered in a bunch on the ground, and he wanted to save them. I told him to set a hive over the bunch, and the bees would go up into it. He did that, and then took the bees home.

"Now we will cut the other tree." It was easy to cut, as it was rotten at the base. This tree stood alone, and had not many limbs—nothing to break the fall. The bees were away up in the top. I got my smoker ready, and then

got out my veil and put it on. "Vell, vell! now vot you going to do now?" the old man said.

"Well," said I, "this is a horse of another color. You see, this tree has got to fall hard, and may be it will split wide open and throw the bees all over the ground. In that case it will be hard to get the bees to behave, as I can not smoke them if they are scattered; so I will put on this veil, then the bees can not sting me in the face."

"Ya, ya; I see now. Dat is a nice ting. Vy you not use him pefore?"

"Why, the other tree fell easy, and I did not have to use the veil. I very seldom use a veil; but I may have to with this tree."

By this time the tree came down crash on the ground. I ran into the top. The tree was not smashed open. I soon found the entrance, and smoked the bees. There were but few coming out. The hard jar had nearly paralyzed them. I went back to the bushes where the men were hid, and put the veil on the old man, and we went and opened the tree and took out the honey. All together we got a large wash-tub nearly full of nice capped honey. I had brought along a six-quart pail, and I filled it with nice honey to use in camp; but when we had all the honey out of the trees and in the tub, and were ready to leave, the old man said, "Vell, Vrance, what you got to put your part of de honey in?"

"Why," said I, "I have this little tin pail."

"Yes, yes; pud dat von't holt half af de hon-ik."

"Oh! well, this is all I want."

You see, as I had found the trees and helped take the honey, he expected me to have half of the honey. When I told him that little painful was all I wanted, he looked at the tub and hefted one side of it. He said, "*Honey, honey, honey*, all vinter—kee-e-e! *honey* all vinter!" and he was as happy as a king.

"Vell," said he, "it do beat all how you handle dose pees. I tinks you know all 'poud dem pees."

Now that we have the trees cut and honey disposed of I want to mention a few things that I noticed. The first tree cut, I would call the colony in it two years old; at least, they had wintered there one winter. The opening in the tree, or the place occupied by the bees, was five feet up and down, or, rather, down, as the entrance into the tree was at the side of the top. The entrance was fully two feet long—a large crack two inches wide at the top end, and running to a point at the lower end—plenty of ventilation at top, none at the bottom. The cavity was small—room in the largest place for only five combs—about eight inches wide. That part of the tree, or hive, was about two feet long. At the upper end there was room for only two combs, and at the bottom for three—pretty small hive, but it was tall. Every comb was full of honey except one piece at the lower

end two by three inches, that had capped brood in it.

The second tree cut was a larger hive—six feet high, top and bottom running to a point like the other; lower end, four combs; top only one comb for the last six inches; the middle of the hive had eight combs $2\frac{1}{2}$ feet; entrance, a round knot-hole $1\frac{1}{2}$ inches in diameter, just below the largest part of the hive. This colony had brood in one comb, three inches wide and six inches high, and was also in the very lowest part of the hive. Those trees were cut about the middle of October, and in height were equal to a six or seven story L. hive. I will ask Mr. C. A. Hatch how it happens that all the brood there was in those two hives was at the very bottom. He says it is easy to get the queen to go up, but not down. It is just as easy for me to see how the queen will go down as readily as up. I always find the queen, in the spring, laying in the highest empty comb, or just below the honey; and if left to themselves she will keep the same place all summer—that is, just below the honey; when the honey-flow comes on she will be driven down and down; and if the honey continues to come she will be driven to the very bottom. In the same way, the queen will follow the honey up when there is none coming in. The bees use the lowest honey first; so the queen works up and down according to circumstances, but keeps just below the honey.

Platteville, Wis.

BEE-ESCAPES.

THE DAYTON ESCAPE CRITICISED; NO ADVANTAGE IN HAVING MORE THAN ONE WAY OF ESCAPE; AN INTERESTING AND VALUABLE ARTICLE.

By R. & E. C. Porter.

Mr. Editor:—In reference to the Dayton escape, and his articles regarding it and escapes in general, permit us to say that, when the article describing it appeared in GLEANINGS, and you asked for the experience of others with it or similar devices, we refrained from responding because we dislike exceedingly to do any thing that savors of "ax-grinding," and do not now wish to say any thing for publication; but in view of what he says in Jan. 1 GLEANINGS we think a few words with you personally regarding the matter may not be out of place.

Mr. Dayton's theories are, perhaps, plausible; but some of these, as well as the claims he makes for his device, and his statement of the results of his experiments with the Porter escape, are at variance with our experience.

In 1890 we tested many forms of trap-door escapes; but all, sooner or later, proved to be impracticable for general use, on account of difficulties arising from propolis and corrosion, and none were found to show any points of superiority over properly made spring escapes.

The form inclosed proved the most nearly successful of any; but in occasional instances, this too was propolized so as to prevent its working.

For experimentation, a number of boards were filled with this form, some with one escape opening into the brood-chamber in the usual way, some having one opening into the brood-chamber, and in addition thereto having one placed in the rim or cleat of the board, opening outside the hive, and admitting light directly to the super, both ends of the body of the escape being open, and some having an escape only in the rim of the board. All of these were carefully tested, comparatively. The first arrangement was found equal to the other two in all respects, and superior in some. The addition of an escape to the rim of the board, and opening outside the hive, admitting light to the super, was not found to shorten the time occupied by the bees in leaving the super in any instance; but, on the contrary, it proved objectionable on account of attracting robber-bees, and causing disturbance of the apiary. With the same device, and at the same time, Mr. S. A. Shuck, of Liverpool, Ill., made for us substantially the same experiments that we made, and with the same results. You will notice that the swinging-gate, or door, in the escape sent you is so delicate that bees in passing under it will pay practically no attention to it. In fact, it is far more delicate than is necessary.

The following clipping from the directions sent out with the Porter escape is a concise statement of the reason that it is made in its present form:

One escape to the board is sufficient. Extensive experiments have shown that a larger number, or one having greater exit capacity, will do the work no more rapidly. Also that the circulation of air through the escape supplies the super at all times with sufficient ventilation.

Before the permanent form of the Porter escape was finally decided on, neither time, pains, nor expense was spared to determine the best possible form. For an entire season it was carefully tested by several expert bee-keepers in a large number of different forms, embracing those in which the bees passed out under the springs, those in which they passed out over them, those in which they passed out between them, those in which they passed out between them and the sides of the escape, those having exits varying in number from one to a dozen, and those in which perforated tin was used for the tops, also for both tops and bodies. After carefully considering the excellencies and defects of all, the form that is now known to the public was decided on as in every way the best; and the universal favor with which it has been received after large and extensive use in all parts of the world leads us to believe that we have made no mistake in our choice; but if we ever find that we have, we shall be only too willing to change it.

On August 4, 1893, after reading Mr. Dayton's criticisms of escapes in the *Review*, we took the pains to send him by mail four Porter escapes

of the usual form—two similar to these, but having exits at both ends, and one with fifteen exits in which the bees passed out under the springs, and we wrote him, asking him, if he cared to do so, to place the four in a board, and test them comparatively, with one of the same kind in a board, and also with the other forms sent, and favor us with the result. But as yet he has taken no notice of either the escape or the letter. We can not doubt that both reached him, as both have request for return if not delivered.

At the same time, to Mr. R. C. Akin, of Colorado, who had also been criticising escapes, we sent a package of escapes identical to that sent to Mr. Dayton. Mr. A. made the test wished for, and reported that he could see no advantage in the large forms, or in using more than one to a board.

Lewistown, Ill., Jan. 5.

[If Mr. Dayton received the package of escapes referred to, perhaps he would have no objection to reporting the result of his experiments with them in these columns. I should be glad to have him do so whenever he is prepared to make such report.

It occurs to me that it would not be a bad idea to send a similar package of escapes to R. L. Taylor, to be tested at the Michigan Experiment Station. We will pay the expense of the escapes, and also of those sent by Mr. Dayton to the same place.—Ed.]

HONEY-HOUSES FOR OUT-APIARIES.

HOW PRACTICED BY W. L. COGGSHALL.
PLAIN, PRACTICAL INSTRUCTIONS; MANAGEMENT OF OUT-YARDS IN GENERAL.

By Harry S. Howe.

It seems to me as though the slight expense of a permanent building is more than balanced by the advantages of having a place where the extractor and other things can be kept under cover and ready for instant use. At the present prices of extracted honey we have got to reduce the work to the fewest possible motions and to the least possible expense if we are to make it profitable.

By having permanent buildings at the out-yards, any one can save a great deal of the expense of transportation. If we are to do as Mr. Coggshall does, and visit two or three yards in a day, and take three or four thousand pounds of honey, we must have the work reduced to a perfect system.

After one or two trips with a team and heavy wagon in the spring, to take the kegs, etc., to the yards, the trips can be made in a buggy, if two or three are to go, or on the wheel if but one, until time to draw away the honey in the fall.

As Mr. C. and I have worked together, one puts out the horse while the other lights the smoker and prepares for work in the yard. By the time the horse is cared for the empty kegs for the day's work have been tested by blowing into them, and we are ready to commence to

take off the honey. When the yard has been gone over, it is an equally short job to pick up and start. One gets the horse while the other goes through the yard and sees that no fire has been left, and attends to any other little matters. Then away we go, three or four miles, to the next one.

Nearly every thing that is likely to be used at the yard is kept there, so there is no forgetting to take some important thing.

Mr. C. wears his veil in his hat all the season, consequently it is always ready. When there is but little to do, one man can get to the yard on a wheel or in a buggy, and go over it very rapidly, if every thing he is to use is there handy.

Mr. C.'s nine houses and my two are all very nearly alike. They are 12x16, and 8 feet high at the eaves, made of rough lumber, but having good floors. Sixteen-foot boards cut in two make the sides; twelve-foot boards, the floor, which must have a good foundation in order to support the weight of the honey, without sagging. The door should be wide enough for the cart or wheelbarrow, or whatever you use to carry in the honey, to go through easily. The windows are the size of one large sash, and slide sidewise to open. They are covered with wire cloth on the outside, and have bee-escapes at the top.

The house should be at the lower side of the yard, and so situated that you can get in without having to go up a high step with a load of honey. Following is a plan of the house:

On entering the door, the first is a stand, just the right height for the filled carryall. Beyond and in front of the window is one of Mr. C.'s own make of four-frame non-reversible extractors, which holds 300 lbs. under the reel. From this the honey passes through a large honey-gate to a ten-quart pail; then into a store-can holding from 300 to 500 lbs., and which is just at the right height to run the honey into the two 110-lb. pine kegs, which are stored in the back part of the room as fast as filled.

We do not usually begin to draw off the honey from the extractor until it is pretty well up, so

there is small need of a strainer; but at the last there is a large one made of cheese-cloth stitched to a hoop that will just go over the store-can, through which it is poured, and which is used to keep any stray bees from getting into the honey. The holes are bored in the heads of the kegs with a one-inch bit as they are taken from the car. The plugs are turned, and are a perfect fit every time. The honey that might get past a poor hand-made plug will soon pay for them at one cent each.

The capping-dish is placed within easy reach of the man who runs the extractor, and also of the one who carries in, so that, whichever one has the most time, can use it.

There is a box for the smoker fuel in the corner, and a shelf for dishes of different-sized nails; wires for broken combs; plugs, etc.; also plenty of nails to hang things up on, and a good brass lock for the door. The parts of the lock must be all brass or it will rust out through the winter. One key will fit the lock to all the honey-houses. There is always a pail of water near the door to wash the fingers if they get sticky; and to keep the whisk-broom, used to brush off the bees, soft and pliable.

We have found it cheaper to keep all the things wanted, at each yard, than to pay for the inevitable breakages and loss of moving extractors, etc., from place to place during the season. It does not take any more room to store the things at each yard than it does at home. Such a house can be put up, in this vicinity, for \$30.00.

The places are rented for a term of years. In some cases the houses are to become the property of the land-owner when the bees go away; in others they are built in sections and put on blocks, so as to be moved. When they are to be left they usually agree to pay a small price for them, or the rent is small enough so that we can afford to leave them.

West Groton, N. Y.

[Such articles as these are just what we want. It is the account of real practical work of what has been done—not what might be done in beautiful theory, that makes interesting and valuable subject-matter. Come again, friend Howe.—ED.]

HONEY AS A DIET.

WILL IT EVER BECOME AN ARTICLE OF COMMON FOOD? ARE BEE KEEPERS SETTING AN EXAMPLE IN THE USE OF HONEY IN THEIR OWN FAMILIES?

It is no doubt very laudable in honey-producers to try to extend the use of honey by getting people accustomed to using it more frequently upon their tables; but we must not be blind to the fact that we have a great deal of prejudice or distaste for honey, real or fancy, to overcome before it becomes a staple article of

diet such as butter, sugar, preserved fruits, and even syrups. Many persons do not like honey; others care but little for it; and I have met several who could not eat it without its making them sick. Housekeepers will naturally cater to the taste of their families and guest, and will not provide an article of food for their table that is not appreciated by the majority, especially if that article is more costly than others that may be substituted for it.

I have traveled some, and visited much in private families. For the last six weeks I have been somewhat of a rambler, and have been the guest of many families in Central Kentucky, known as the rich blue-grass country. I can not now remember of ever seeing honey on the table of a hotel; and in my late rambles I have not met with it on the tables of private families. Speaking to a most excellent matron whose table is very bountifully supplied both with the substantial of life and most of the luxuries that can be bought, she said her family cared very little for honey; and as for herself she would not give one jar of peach marmalade for all the honey in the world, and hence she did not provide it for her table.

Molasses or syrups I have found at the hotels generally, and quite often in private families. The low price of these, and of sugar, and the more general production and use of fruit, all combine to lessen the use of honey.

I do not wish to discourage bee-keepers from trying to make the use of honey more common; in fact, that should be our object; but it is best to look the facts squarely in the face, and I must admit that they seem to be against the use of honey as a common article of food.

What can we do to increase the use of honey? This is a question that I am not prepared to answer satisfactorily, even to myself. We might set an example by using more of it upon our own table. Last winter we had honey regularly three times a day upon our table, and continued to have it more or less all the year round. We would vary it—extracted honey candied; extracted dissolved, and comb honey. But I must be candid, and say it was seldom tasted except by myself and one other member of my family. I am a lover of honey, and do not often let an opportunity pass without eating it. I think that I individually eat not less than 50 lbs. a year. There are so few ways that honey can be used, other than to eat it upon your bread and pancakes, that its use must continue to be limited. In cooking, sugar is better and cheaper. I have tried it upon my porridge, upon my fruit, and in my coffee. My wife, to please me, made cakes sweetened with it; but as great a lover of honey as I am, I must confess that I prefer sugar for these purposes.

What are other bee-keepers doing to increase the use in their own families? How often is honey placed upon the table of our friends at the Home of the Honey-bee, where honey is

plentiful and cheap? and how about its use in other bee-keepers' families?

But, of course, something else must be done. The price of honey is, undeniably, high when compared with other sweets and fruits that come in competition with it. Will the price have to come down? and can we afford to produce it profitably at a lower price? or shall we maintain the price and limit the production to the amount consumed by those who use it only as a luxury? These are questions which I must leave to be answered by those who are extensively in the business.

NOTES AND COMMENTS ON THE A B C.

IDEAS OF AN AUSTRALIAN.

By E. James.

I have been much interested in reading your A B C book. I am a practical bee-keeper, and have been working 200 hives in Queensland; but a flood unfortunately swept away years of hard toil in a few hours; but "nil desperandum" is my motto. I love the grand colony of Queensland yet.

I will give you some of my practical experience in bee-keeping in this glorious country of Australia, as no continent in the world possesses such a climate, especially for bees.

1. I was reading in the A B C about smokers. There seems to be a lot of inventive skill thrown away upon them. I prefer the Bingham smoker, with the blast through the fuel; but it is the fuel used that is the question. One day I happened to pick up a piece of bark off a box (a species of eucalyptus-tree), and placed it in the smoker, when I found it gave off an immense volume of smoke; and since then I have used no other fuel.

I have tried a great many kinds of hives, but I have not been satisfied with any of the new-fangled notions. I have come to the conclusion, after considerable practice, that a modified Langstroth-Heddon combination seems to give me more satisfaction than any I have yet used.

The brood-section is the same size all around

as the Langstroth, but the supers are 8 in. deep. The frames are a modification of the broad-end Quinby, with this exception: the ends of the frames are beveled, or chamfered, as shown at A in Fig. 6. Should the bees build comb up to the end, the frame and case come out quite easily.

Another idea I have is in the line of self-swarming. Place an empty hive in front of the one expected to swarm. I have a thin piece of board with a piece of zinc or tin nailed flat on each end, like a flap. The whole is covered with regulation perforated zinc, as shown in Fig. 7, forming a gangway. Each end at A A is zinc, so it lies close to the entrance of the hive. I have never lost a swarm.

BUZZ-SAWS.

I have recently constructed a saw-bench to work with the foot, and it works to my entire

satisfaction—rips any thing required in an apary. It is much like the hand buzz-saw shown in the A B C, except that there are no cog-wheels; the saw-arbor turns on centers at each end. There is a small hard-wood pulley on the saw-arbor, three inches in diameter, which is driven by a fly-wheel and strap two inches. The fly-wheel is 27 inches in diameter. On the saw-arbor is a fly-wheel from an old sewing-machine, which gives the necessary momentum. The top of the bench is of cedar, one inch thick, hinged at one end. The other end can be raised or lowered as desired, for grooving, rabbeting, etc. Carpenters have had the loan of the bench, and were delighted with it. I have tried benches made on the principle of the Seneca Falls Mfg. Co.'s benches, but it takes too long to speed up, and I had to discard them—too much friction.

A REVERSING EXTRACTOR.

I have also an extractor—quite a new and novel idea. Each cage turns upon a center, as

shown in Figs. 1 and 2. Inside the iron or steel frame are centers, as at A A. By placing the hand on the top of the cage it is inclined outwardly instantly, and the frame can be taken out or inserted quite easily.

The honey comes out splendidly in my extractor, whichever way I turn.

I is a steel frame; C, cage; P, pivot. In this extractor there is no knack or habit to acquire. In placing the frame in the extractor, put the hand on the top, and draw the top of the cage outward; place the frame in, and the cage falls back into its place by its own gravity. When each cage has been operated upon thus, the extractor is ready. When the one side of the comb has been thoroughly extracted, all one has to do is to reverse the extractor, and the four cages are reversed at one operation. There is little or no jerking, nor any undue strain, as in the Stanley. Four steel arms are required to hold the cages, keyed on the center-shaft. Nothing is required to steady the cages at the lower end. I am not a first-class draftsman, but I hope I have made myself clear.

The cut above shows top view of extractor. A A A A are cages for holding frames. B B B B are arms, the center being loose on the upright shaft C; but the arms turn around with the cages. On turning the machine the cages are brought into position as per diagram; reverse the extractor, and the cages are completely reversed; although each cage hangs on a pivot at each side, the cages are self-reversing; there is no jerking, as in the Stanley, nor any thing to get out of order. I have a bevel gear to drive it, slightly stronger than your extractor. The frames are so weighty when filled with honey that the teeth of the gear strip or break—at least, that is my experience.

have known frames to weigh 12 to 13 lbs. with honey.

Australia is a prolific country for bees and bee-food. The various species of eucalypti are wonderful, especially box, gray, and black. More honey is procured on what is known here as the "open box-plains." Here are some figures:

MESSNER'S BEE-FARM.

Williamstown, South Australia, June 18th, 1892; 250 hives produced 47 tons of honey. One colony yielded 45 lbs. of honey per week, or 700 lbs. per season. Not far from where I am, H. Peterson, Wattle Flat, N. S. W., had one hive that yielded 1250 lbs.; 190 hives produced 22 tons, sold for 28 pounds (\$135) per ton, principally from gray box (eucalyptus).

Peak Hill, Australia, Oct. 17.

[Some of your inventions, although ingenious, are quite old in practice. I refer particularly to Fig. 6, the position of the frames, and to the reversing-gear of your extractor. The former idea you will find in looking up Mr. Cowan's book, the "Bee-keeper's Guide," as devised by the author, Mr. Cowan, away back in 1875. But I do not wish to carry the idea that, because these ideas are old, they are therefore

lacking in merit; for, indeed, the Cowan extractor that we are now using, and which has been recently indorsed by the whole bee-keeping world on this side of the Atlantic, was devised some three years earlier yet.—Ed.]

RAMBLE 125.

By Rambler.

IN THE SANTA CRUZ MOUNTAINS.

From the city of Santa Cruz we could see the frowning peaks of the Santa Cruz Mountains. We knew from past experience that they were a toilsome barrier between us and the country we wished to visit beyond. But why should we question the dark canyons and the heights to climb? Had we not surmounted the San Fernando Mountains? yes, and the Santa Yñez? yes, and the Santa Lucia and the Cuesta Pass? yes, and they were all a memory of the past, and we set our faces confidently and resolutely to the surmounting of this barrier also.

As we entered the mountainous region our road led us through a series of romantic drives. We followed the San Lorenzo River, and, after passing an extensive tannery, with its variety of bad odors, we came again into the redwood belt. The smaller trees and undergrowth arched our winding roadway, and the vistas we often caught of waterfalls, forest, and mountains, rustic bridge, and wayside cabins, made the day of travel full of pleasure.

As we slowly toiled up the grade we passed a building fenced with great care. So high was the fence that we could scarcely discern the buildings beyond. A mile or more beyond, again another series of buildings, fenced, gates locked, a forbidding sign, "No admittance." We surmise, "Why all this fencing? too much for poultry-ranches; too elaborate for bee-ranches, for bee-ranches are not fenced in California." Then again we came to fenced buildings; but this time we evidently come to the center of operations, and blazoned to the world in large letters we find the sign, "Powder-works!" So here in a series of buildings, scattered for several miles along the river, explosives of various kinds are manufactured. The buildings are fenced against outside intruders, and located far apart, so that, if an explosion occurs in one building, the next, a mile or more away, will be free from the blowing-up contagion. The powder-works and the tannery below called for much teaming on this mountain road, and loads of wood and bark were constantly met. Five horses to the wagon was the rule—three abreast next the wagon, and two ahead; long-drawn-out teams could not be managed on these sharp curves, so the horses were driven in a bunch, so to speak.

Near Felton our redwoods became so large as to be noted, and visitors are attracted from the highway to visit Gen. Grant and Sherman, and a few lesser lights. As we expected to see

much larger trees we did not bend our course to visit them, but kept on our way. The day was well spent; our ponies were showing signs of fatigue; and while we were considering the advisability of camping, we saw from our forest-canopied road an enticing sign which read, "Lemonaide, 5 cts. a glass." And surely our eyes beheld there among the rocks and trees, and near to a purling stream, an apology for a tent, and a sturdy German stood by the roadside.

The tenor of our conversation, when we halted in front of the sign, was for a good camping-place.

"Dis is der best blace on der road. Durn right in dere," said he, pointing to an obscure opening in the bushes. "Trive town a leedle vays till you comes to ter prook; camp dhere; von goot blace."

Then Bro. Wilder put in his next invariable inquiry: "Is there good hunting in these mountains?"

"Hunting? Mine cracious! dere's lots off it—teers all ofer dese mountains; dere's von oldt pig fellow gomes town into der roat sometimes, shust at night, sometimes shust in der morning, mit horns so vide;" and he stretched his arms to their full extent. "I ton't see how he gets troo dese woods. No, mine cracious! I ton't. Den dere's mountain-lions. I hears two, sometimes dree, roaring like furies on der mountains. Oh, yes! dis vas a creat game goondry; and dere's vish in der river—creat pig vish, may pe veigh von, do, dree, and may pe *seer* point." Just imagine the effect this highly colored news had upon my partner. He was all wrought up for game; and, donning his hunting-equipments, he plunged into the forest. After setting our camp in order I pulled out our fishing-tackle and proceeded in a more quiet way to try the mountain stream. A few trout arose to the bait; but those "von, do, dree, *seer*" pounders were shy of the hook, and I had to content myself with much smaller fry.

Wilder's deer-hunt resulted only in signs. Signs were plentiful where "dose horns, so vide" had knocked the bark off the trees. The only signs of mountain-lions was the hole they had left in the air, with their roar.

A friendly call upon our German in the evening revealed the fact that he was an ex-saloon-keeper. The authorities in a little town near by had high-licensed and otherwise taxed him so high that he had moved out of town, and he felt as though he was a much-abused man. Many teams passed this obscure retreat of his,

and no doubt he sold much "lemonade at 5 cts. per glass."

Our trout breakfast disposed of, we proceeded to climb the long and winding grade to the very summit of the mountain. For nearly fifteen miles we climbed steadily upward. Many times our road led around gorges so deep that we could look into the tops of trees whose base was planted 150 or 200 feet below us. The mountain is quite densely wooded until we near the top. It was here, while rounding a spur in the open, that Wilder grasped his rifle again, and, pointing across to the hill beyond, exclaimed in a sort of stage whisper, "A deer! a deer! Just let me have a chance at him."

We both hustled out of the wagon. It was a long shot; and while the sights were being set the field-glass was suggested as the proper in-

"DHERE VAS TEER MIT HORNS SO VIDE!"

strument to bear upon the animal; and what do you think it revealed? I had to laugh rather immoderately when the glass showed a *bona-fide* donkey. It seemed, through the glass, that he had a sort of grimace on his benign countenance. At any rate, it was a sign of deer that Bro. Wilder did not like, and he was worked up to such a pitch that he said not another word for many miles. As indicated by the donkey, we found the very summit of the mountain inhabited. A large number of Swiss people, true to their mountain habits, have here made their

homes, and cultivate land that, to an ordinary mortal, would seem to be hung up too much edgewise. We saw fields of oats and other grains that were certainly upon land lying at an angle of 45°. The only way that crops could be harvested from these steep hillsides was with a half-cart half-sleigh arrangement, and small loads the rule. The land seemed very productive, and, besides grain, grapes and other fruits were largely planted. The scenery from

ously killed when the owner wanted a taste of honey.

In this portion of the Santa Clara Valley the soil was admirably adapted to the raising of onion-seed, and hundreds of acres were coming to ripened heads. Chinese labor was seen gathering the heads and beating out the seed with the old-time flail. We neglected to hunt up the man with the hundred colonies of bees; but it occurred to us that, near these onion-fields, almond and fruit orchards would be a profitable place to plant an apiary.

For over 250 miles we have traveled now through the coast counties; and not since we left Ventura have we found many bee-keepers. Isolated apiaries we have found in the lower counties; and that there are good localities for profitable bee-keeping in all of the counties, there is no doubt; for wherever we rambled on the barren plain, in the dark canyon, or on the mountain-tops, wherever an opening flower spread its petals to the sun, there we found the busy bee, showing that the little wonder-worker has indeed taken possession of this Western World, and through this fact alone the honey-bee has the profound admiration of the Rambler.

A DEER, AND WHAT THE GLASS REVEALED.

these heights, as we looked out upon the mountains until they shaded off into the dim distance, was grand and inspiring to the beholder.

Our drive down the other side of the mountain was rapid. Our ponies kicked up a terrible dust, and it was in a dusty condition that we entered the beautiful town of Los Gatos. We were now in the famous and fertile Santa Clara Valley. We found a series of thriving towns, of which San Jose is the crowning center.

Apricot-orchards were without end; in fact, the apricot is to San Jose what the orange is to Riverside and the grape to Fresno.

We camp again at Warm Springs, and this time we were happily located near an old schoolhouse. The good people of the neighborhood, to the number of ten, including the Rambler, assembled that evening in a meeting of prayer and singing. Several young men were in attendance, showing that the leaven of the Christian religion was working in the right direction. One of these young men gave us the information that there were but few bees kept in that vicinity. The largest apiary that he knew of for many miles was further down the valley, and contained 100 colonies. His father, he said, kept a few colonies in his almond-orchard. The almond is profuse in blossoms, and this gentleman found that he had more nuts upon his trees if the bees were there to aid in pollination. The honey from the almond he pronounced fine. Their bees were kept in a non-scientific way, and the bees were barbar-

CALIFORNIA NUGGETS.

HOW TO CONSTRUCT A PERCOLATOR; HOW TO KILL A LOT OF KINGBIRDS AT ONE SHOT.

By C. W. Dayton.

In California the antipathy of the fruit-man against bees is equaled by that of him who is trying to dispose of a tract of \$10-per-acre land at \$100 per lot.

The best sign-board and the best advertisement for honey is thirty or forty colonies sitting in the front yard. People dislike to buy honey of those who do not keep bees. It is like milk in a large city—the dairy product is preferred.

A feeder beneath the brood-apartment is preferable in "feeding back" honey to complete sections, as the bees "clean their feet" while traversing the brood-combs. If feeding for winter stores, place the feeder above, as the feed will be taken down faster, it seems to me.

If your apiary is strewn with leaves, as you walk along after dusk toads will be heard rustling the leaves. One way is to gather them up by hand; but a better plan is to sink a few boxes in the earth, level with their upper edges, for the toads to fall into, and deep enough so that they are unable to jump out.

Since it is admitted that kingbirds destroy bees, the next thing is to find a plan to destroy the kingbirds without the expense of a charge of shot and powder, and the time it takes for each bird. Stretch a fence-wire between two trees in line with an upstairs window of the house or barn. In the absence of trees, use high posts. In the absence of such window, let

one post be enough shorter than the other to sight along the wire while standing on the ground. Wait until several birds collect upon the wire, and then clear them off at one shot.

Propolis is suggested as an exterminator of the bee-moth. In using covers to the brood-nests, which are composed of three boards cleated together when new, water ran through into the hives. It also soaked in around the edges, and dropped off near the center of the hives. Since two seasons' use and propolization, they remain dry on the under side through the heaviest and longest rains. If the upper side becomes water-soaked, the under side continues glassy and impervious. It might be added that the covers were of redwood, which is the only kind of wood which does not shrink sideways. The result might be different with pine.

Mr. W. A. Wheeler recommends salicylic acid and powdered borax in water as a cure for bee-paralysis. I wonder if the acid alone would not do as well. If not, then would not the borax alone cure it? If nothing short of the mixture will suffice, it would be interesting to know how the discoverer was able to hit upon the exact specific instead of hitting a million others which might be guessed at. I am thankful for the cure, even if the explanation is not obtainable. I have not lost faith in my own cure (superseding of queens), but I have three cases so early in the season that queens can not be reared. But the acid cure can be applied now. The season of 1893 was a good one for honey, and also a good one for paralysis. Last season was poor for honey, and there were no new cases of paralysis. Now, my wonder is, whether the appearance of paralysis so promptly may not be an indication of an abundant honey-flow in 1895.

To construct a percolator, first get a sixteen-foot board, 14 inches wide, and cut it into four pieces of equal length. Bevel each piece, and nail together so as to form a box 12 inches square at the top and 8 at the bottom, sloping like a mill-hopper. For a bottom to the hopper, get out a small board eight inches square and tack around its outer edge a strip of thick felt to prevent syrup getting through next the outside. This bottom may be dropped inside and allowed to seek its own position. In the center, cut an aperture five inches in diameter, and tack over the same a piece of extractor-screen wire which exceeds the size of the aperture, but should not extend to the margin of the board. Spread over the screen a thin layer of cotton batting, and over the batting another piece of screen to keep the batting in position. Of the waste lumber remaining from the side pieces make four legs by sawing to the right level and nailing to the center of each side. It should be high enough from the floor to set a five-gallon honey-can under. The capacity of the percolator will vary according to the thick-

ness of the cotton batting, the quantity of sugar, and the depth of water. If this percolator is kept full, the yield will be about 20 gallons of thick syrup in 24 hours.

Florence, Cal.

[Your percolator, I feel quite sure, would work, judging from what experience I have had with percolators.—Ed.]

WILLIE ATCHLEY'S EXPERIMENT.

DRONES FROM LAYING WORKERS OR UNFECUNDATED QUEENS; ELEMENTS OF UNCERTAINTY.

By Dr. C. C. Miller.

It is interesting to learn of the experiment reported by Willie Atchley on page 19. For the honey-raiser the matter may be of no particular interest, for he is not likely to have queens mated at any time when drones of undoubted virility and vigor do not abound; but if it be an error to suppose that drones are equally good, we may as well know it; otherwise there might be trouble come from keeping bad drones to use out of season, for it is easier to keep drones in a colony with a drone-laying queen or with laying workers.

That one experiment, however, should not be considered conclusive. Elements of uncertainty may be present unsuspected. Moreover, there is a little cloudiness, apparently, in the conclusions reached, or that seem to be reached; for although the experiment did not involve drones from unfecundated queens, yet Willie says, "I am now fully convinced that I do not want any of my queens mated with any but drones from best fertilized queens." Suppose that it be fully established that drones from laying workers are utterly worthless, does it necessarily follow that drones from an unfecundated queen are any thing but the best?

We should be the more slow at reaching conclusions, because, if I mistake not, the book authorities, where they are not entirely silent on the subject, agree in giving drones credit for value from whatever source they may come. Berlepsch, a man who stands high as an authority, says: "The eggs laid by fertile workers produce perfect drones. I firmly believe this, because the drones thus produced precisely resemble, in every respect, those bred in colonies having fully fertile queens." See *American Bee Journal*, 1861, page 146. Dzierzon, page 24, *Rational Bee-keeping*, says, "As in every respect they are like drones originating from a queen, there is no reason why they should not also possess all the capabilities of the latter."

Cheshire says, "The powers of the drone just described are, almost with certainty, not alone true for those brought up in the normal cells of their sex, the issue of a fertilized mother, but for all indifferently. Hereafter we shall more fully explain that the egg yielding the drone is

unfertilized, so that those born of mothers that have never mated (drone-breeders) are as perfectly developed and as fully virile as others. Dwarf drones also, raised accidentally in worker-cells, or those from the eggs of so-called fertile workers, or workers which, although incapable of impregnation, have yet commenced ovipositing, seem not one whit behind the rest."

It will be noticed, however, that, however high these authorities, their views are not based upon actual experiment, so that, although we should be careful about reaching any opposite conclusion, it is certainly reasonable for us to say that the case is not entirely closed. I would give more for the results of a sufficient number of experiments in the hands of careful observers than for the theoretical views of all the scientists.

Willie says, "I am perfectly satisfied that the queen has the power to deposit eggs without having them come in contact with the semen, or fluid deposited by the drone, and *all* such produce drones. I should be glad indeed to have some of the old heads take this thing in hand, say Doolittle or Prof. Cook, and see if I am not right." Of course, you're right, Willie; but, bless your heart, there's no need for any one to take it in hand. That question was fully settled before you were born. Look at the first volume of the *American Bee Journal*, 1861, and you will see the matter fully discussed and settled in the series of papers on the Dzierzon theory.

At present there is a large amount of theory and a small amount of practice to settle the value of abnormal drones. That being the case, it can hardly be presumptuous to theorize a little more right here.

A worker is not a fully developed female; and although there may be more development in a laying worker than in an ordinary worker, still there is not a full development of the organs of reproduction, and on that account one would hardly expect as good progeny as from a female fully developed in all the parts that in any way have to do with providing and furnishing a vigorous offspring. The worker was never intended for a mother in the first place, and one would hardly expect her to be an unqualified success in that direction. The experiment of Willie Atchley, while in itself not conclusive, is valuable in that it goes just so far toward establishing as a fact, that the offspring of laying workers do not equal those of fully developed queens.

With regard to drones from unfecundated queens, Willie has a rather cavalier fashion of settling the question by manufacturing a definition to fit the case. An undeveloped drone, says he, is a drone from any but a fertilized queen. As we want a fully developed animal for a sire, that at once settles the case, and there is no need of any further experiment. But is it fully established that a drone from an

unimpregnated mother is not as fully developed as one from an impregnated mother? The argument seems to be that the drone is undeveloped because the mother is undeveloped, "as we all know that a queen is not thoroughly developed till she is mated and begins to lay." Do we all know that? Is the fecundation of a female a part of its development? Take two flocks of hens, the one flock fully developed in every respect, and having a cock in the coop; the other precisely the same, except that the cock has been carefully excluded, would you say there was any lack of development in the latter case? Is there no case of full development among the thousands of mares that are never used for breeding-purposes?

Here's a choice tested queen fully developed. How much did her fecundation contribute to her development? Suppose her wings had been clipped during her virginity. Would her development have stopped? Would she not have grown to the same size as now? Would she not have been the same in every respect as now, with the single exception of an empty spermatheca? And in the case of the tested queen, does that spermatheca have any thing whatever to do with the eggs laid in drone-cells?

I don't know the answer to all these questions, and I should want somewhat positive answers before settling down to the belief that a queen can not be mother to a fully developed drone just as well without as with fecundation.

A point still to be noticed is, that a drone-laying queen, even if it should be fully proven that she can raise the best of drones, in actual practice does not raise, or, rather, from her eggs there are not raised, drones of normal size, simply because they are mostly raised in worker-cells; and I think no one would be so well satisfied with drones below the normal size.

On the whole I commend the decision reached, which is seconded by the A B C, to raise drones from only the best fecundated queens.

Marengo, Ill.

LARGE AND SMALL HIVES.

A GOLDEN MEAN: HOFFMAN FRAMES, ETC.

By H. L. Jeffrey.

Mr. Editor:—On page 952, 1894, I note your editorial, "Large and Small Hives, Again." There, as in other places, you refer to the ten, twelve, and sixteen frame hives. Now, just let me tell you that you are not fresh or new in that line of the number of frames; but before going into the experience points I will refer you back to GLEANINGS of twelve or thirteen years ago—1881 or 1882, perhaps 1883—as a proof of what I am going to say, and I will quote from memory, and let you look up the proof of the date; and yet in practice I can go back fifteen or sixteen years. Twelve or thirteen years ago I wrote to A. I. Root from Washington, Ct., that

I was using what I called the Simplicity chaff hive—a hive 18½ inches square inside, with three or four inches of packing at each end of the frames. The hive stood on a chaff-packed bottom-board, and at the *sides* I used a cushion or chaff-packed frame, cloth on one side and thin boards on the other side, turning the cloth toward the bees in winter, contracting the brood-nest to four, five, or six combs, as it was necessary; and in the spring, as early as convenient, I cleaned out the hive and turned the *board* side of these side cushions toward the bees. When I nailed on these board sides, in the first place I laid two or more thicknesses of cloth on the ends and bottom of this side frame, and let the cloth project from ¾ to ½ inch beyond the frame. The cloth is used as a heat retainer or confiner, to prevent the heat from escaping around the end of the frame.

Well, those thirteen-frame hives very often had eleven frames of solid brood, except the top corners of the frames that were filled for three or four inches with pollen and honey; and, what is more, they not often swarmed. I used two styles of surplus-cases on them. One was the wide frame for 8 sections; the other, a case for 4 sections in a row, to place the sections cross-wise of the frames, and use separators, ten sections from front to rear, making 40 sections to the one-tier case, and using two cases high. The sides of these hives were 28 inches long, because they were made of ¾ lumber.

Now for the reasons of the chaff *ends* to the hives: I had always noticed that, in winter, in the single-walled hives, hoar frost or needles of ice formed between the ends of the frames; and by this packing I got rid of that frost in the hives. Then in the case of the 18½ inches in the width of the hive, I had a place to use a side frame of 8 sections at each side, and a half-inch division-board with eight or nine brood-frames before the bees were so numerous as to necessitate putting on a top case.

Besides these large hives I used others, varying from seven frames up to thirteen. At that time, and for thirteen or more years, I was taking care of bees for other people, either wholly myself or by supervision, besides taking care of my own bees, and for years I had the charge of from 100 to 300 hives of bees, located in six or eight towns, in apiaries varying from six or seven hives up to sixty.

A good many objected to these large hives because of their expense, as they had, besides this chaff-packed end and chaff-packed bottom, an outside shell 12 to 15 inches deep, that, for winter, was let down to the bottom, and in summer it was raised so the lower edge was 2 inches below the top of the hive-body, and a cleated and rimmed-top cover. Because of the objection of expense, and the inconvenience of handling and moving these large hives, I made and used for other persons hives holding ten and eight frames; and I can, from experience and close

comparison during years of practical use, say that the large hives were, in dollars and cents, and profitable results, every way the least expensive. But if you will take a pencil, and figure up every thing, the figuring will prove that these large hives cost the most every time, and that is where figures do actually and practically lie. But with the practice of fewer hives, and the time of changing place to work from one hive to another, the time of hiving swarms, and I could name a dozen other items, to say nothing of the larger number of finished sections from each hive, that alone is item enough to make the preference for the large hive. But when you go above that limit of the square, 18½ inches by 9½, then you can just stop—just step down and out. That I have tried, and had to own up beat.

THE HOFFMAN FRAME—WHY I LIKE IT AND WHY I DON'T LIKE IT.

It is not the spacing and fixedness of it that are its best features, but I will admit that the spaced stationary feature of the Hoffman frame is reason enough to make it universally adopted. On account of the forming of ice at the ends of the frames being the reason for using packing at the ends of the hives, I adopted the Hoffman frame in 1879. A pattern of this I obtained from J. H. Nellis, with the wide part of the end-bar made wide for 5 inches, which gave me very gratifying results; but these results the first season only raised the question of how I was to get rid of a cursed nuisance that I had heard more cursing and swearing about than would be necessary to send all the employes of A. I. Root to satanic regions; that is, the plastering of comb and honey at the ends of the combs in the hive. How many hundreds of times I have seen the plastering done when there happened to be one of those sudden heavy flows of honey! and that very disgusting thing happened in 1893 and 1894 with the Hoffman frames that you have sent out with those short wide ends. Only this past season I was called twice to tell parties what to do to stop the trouble of having the honey there at the ends of the frames, and both parties said they wished the ones who made the frames and hives were—not in heaven—"further than they were out of it."

Now, then, friend Root, make that wide part just ¾ of the length of the end of the frame; make the ends fully ¾ thick, and stop that sharpening of the edge. You go and see how many will be shoved by each other, and hear the swearing that I have heard, and you will make no more sharp edges to cause cursing.

I began using the Hoffman frame in 1878. In 1879 and 1880 I used a few with the end-bars 1½ wide the whole length, and I began to practice reversing them; and after 14 years' use, in all sorts of places, I am forced to say, give me the full-length 1½-wide end-bar, just ¾ thick; and having used 3000 pair of your reversing-wires, I do not want wood rests, for two reasons: 1.

They are more easily pried up; and the chief and second reason is, turning combs over does pay, especially when it is the cause of making the bees finish a crate of sections, to say nothing of being a convenient way to make a swarm stay at home when it is put back the next day after swarming; and those solid combs are, beyond dispute, a very great hindrance to swarming, because, without that lower space between the bottom of the comb and bottom-bar, there is no great inducement to build those cups that are such a coaxing inducement to the queen to lay in them, and send things swarming fever fashion.

A LIMIT TO THE NUMBER OF FRAMES THAT MAY BE USED IN THE HIVE.

I feel sure—yes, I can say that I *know*—there is a limit to the practical use of the number of frames used side by side. You have said, "While ten frames may give slightly better results, a twelve or sixteen frame brood-nest would give still better results." Just stop, before you, by such insinuations, "make thy brother to err." It takes years to prove such a statement to be practically true. I will admit the twelve; but fourteen I shall watch and wait, doubt and disbelieve, discourage and denounce; and the sixteen I shall discard and condemn.

Right here I will say that there are many who will say to you, "Bring on your queens to fill and keep full of brood those twelve-frame hives." Such queens have lived; such queens now do live, and such queens there will be. I have had them live to be four years old, and not so very few of them live five years in those thirteen-frame hives, and have kept their workers humming each year, so that it made me as well as other persons wonder whether those large hives did not make the queens better than the small hives; or, in other words, did not those small hives restrict a queen to such an extent that she was in some way injured by a lack of room? How does that strike you? There surely has been some evidence in favor of unlimited space being beneficial; and it is true beyond denial, in all nature, that restricting natural functions is detrimental to both life and health. Larger hives, solid combs, and queens reared out of the swarming season, are the non-swarming climax.

You may tell Mr. E. F. Quigley, p. 951, 1894, that those very late queens are the least likely to swarm — are the steadiest layers, live the longest of any queens, and are the strongest of any, because they are not exhausted while young, in early production. The proof of the pudding is in the eating of it. For years I have raised very late queens entirely, for my own use, and I have written several times about their superiority, although I have never seen the articles in print.

Woodbury, Ct.

[I do not know where you get your foundation

for thinking that I claimed for myself priority on the question of the desirability of large hives. I am, and have been, well aware that it has been brought up a number of times through our back volumes. But in former times it was dropped before any thing definite could be arrived at. My purpose has been to focus down the experience of our best bee-men into something more tangible along these lines, and a little light is beginning to break already, I am thinking.

You fail to give the *whole* of the sentence regarding ten and sixteen frames you quote, and thus give a wrong impression. I said, if you will refer again to page 952, that "I am coming more and more to believe that" such would be the case. I haven't come to that belief yet. The sentence as a whole was suggestive rather than positive, and for the purpose of calling out reports from others; and among those already received, yours is one.

As to that "cussed nuisance," there may have been some occasion for it in the case of the old Simplicity hive when the space was $\frac{3}{8}$ of an inch between the end-bars and the end of the hive. But in the Dove-tailed hives, with the space only $\frac{1}{4}$ inch, we have never heard of there being any trouble. Your experience seems to be at variance with that of the whole bee-keeping fraternity. When almost everybody was using the regular Langstroth frame with its narrow end-bar—narrow clear up—we scarcely heard of burr-combs being deposited back of them, except where the bee-space was more than $\frac{1}{4}$ of an inch.

As to the wide part of the Hoffman end-bars, the length that we use is in proportion to the depth of frame used by Hoffman. I have tried them (the wide part) deeper, but I did not like them so.

Mr. J. has suggested some practical thoughts, although I think he is inclined to put some things overstrong.—Ed.]

TWO EIGHT-FRAME HIVES NOT MAKING A SUITABLE BROOD-NEST, AND WHY.

I was much interested in Mr. Chrysler's letter, on page 948. It chimed in with my experience exactly, so far as my experience goes. I ran a dozen colonies last season in two-story eight-frame hives; it worked pretty well until the honey-flow came, and then in some of them there was a marked inequality between the upper and lower stories, and two of them finally confined themselves to a single story—one using the upper story for brood, and one the lower.

By this time, thanks to your impartial leadership, a little light is being shed on the subject—it is not altogether the mystery it formerly was. But there is one thing not yet satisfactorily presented. Most bee-keepers raise comb-honey, and how in the world is the two-story eight-frame to be recommended to them? There is too much lifting and manipulation connected with it. If the majority of bee-keepers ever get to using brood-chambers of large capacity, I am inclined to think they will "flop" just as Mr. Chrysler did, and as I propose to do. But, let's hear all sides. I would suggest, as the next thing in order, that you get an exhaustive article from E. France, theoretical and practical, on the subject, "Why the two-story eight-frame is to be preferred to all

others for *comb honey*." Then get somebody of experience on the other side (like Dadant) to answer Mr. France's point in detail. We are not through with the hive discussion yet.

Put the case of a man who winters his bees on the summer stands: How much lifting will he have to do, ordinarily? The argument of weight has been made too much of. It is not a general, but a special consideration.

Arvada, Col., Dec. 24. F. L. THOMPSON.

[Mr. France has already set forth his views on this question—see page 45, Jan. 15th issue. Yes, we should be glad to have the Dadants review this whole question from their standpoint, if they will. For many years they championed large hives alone. Now that there are more on their side, perhaps they can set forth their views with more assurance.—Ed.]

GUARDING AGAINST STARVATION.

Question.—What is the best way to guard against bees starving before feeding can be done in the spring? I have fears that my bees have not honey enough to carry them through till warm weather comes.

Answer.—As our questioner asks for "the best way to guard against bees starving," I am inclined to answer that the *best* way is to *know* that each colony has sufficient honey or stores in the fall to last it till the flowers bloom in the spring; and if we know this we need have no fears as to their safety along this line. But some one will ask, "How much stores should each colony have that I may know that there is no danger of starvation?" That is right; ask all such questions you like, for in former years it was just such little things as these which bothered me, and, strange to say, these little things, as most bee-keepers call them, were the hardest questions to find answered in our bee-papers. I hunted through volumes before I could find the amount, given by any writer, that it would take to winter a colony of bees safely from October till May, doing this hunting in the columns of the bee-papers published prior to 1875. The amount which I found first, gave 35 lbs. of actual stores as being the right amount of food necessary to carry a colony through. This almost staggered me, as I had found by weighing the combs of honey in each hive, that not one of my colonies contained that amount, while very few contained 30 lbs. So I kept on looking, when, after a while, I found another writer giving 25 lbs. as sufficient to winter a colony which was to stay all winter on its summer stand, and 20 lbs. for those colonies which were to be wintered in the cellar, during the four months of the coldest weather. "Here," said I, "is some-

thing worth more to me, just at this time, than all I have paid out for bee-papers up to the present;" for had I been obliged to make the stores in all my colonies up to 35 lbs., the sugar would have cost me much more than all I had paid out for bee-books and paper so far.

To digress a little, I wish to say that hardly a year passes, even after I have been constantly reading up bee-literature for the past 25 years, but that I find something during the year that is of more value to me than all the bee-papers have cost me for that 25 years, and yet not a fourth of the bee-keepers in the United States take any bee-paper. I never could understand this penny-wise-and-pound-foolish plan that so many adopt when you urge them to take one or more bee-papers. But to return:

By exchanging combs with my colonies I was enabled to give each colony wintered outdoors, 25 lbs., and 20 lbs. to those wintered in the cellar, and found all came out well; so I set these figures down as the right amount of stores for safe wintering from flowers in the fall to flowers giving honey in the spring; and to-day, about 17 years having passed since I read that statement, I would advise the above amounts as being correct for the beginner to put as the standard. But it will be noted that our correspondent does not say from flowers to flowers, but till "feeding can be done in the spring." Well, how much is needed in this case? This is something different, and something not often spoken about, yet it is something we should like to know about; for I claim that, if there is any time when it is profitable to feed colonies to keep them from starving, it is in the spring of the year. Why? Because if we let them die now we lose all they have consumed thus far; and, besides, feeding in the spring gets the colony in the very best possible shape to give a big yield of honey during the honey harvest; and as this latter is conceded by all, it is often to our advantage to reserve the feeding necessary to be done to give sufficient stores during April and May, till April and May arrive, providing we can know that no colony will starve before that time. One fall I found my colonies quite light; and as I was short of money to buy sugar with, I allowed only 18 lbs. to each colony designed to be wintered on its summer stand, and from 12 to 14 for those to be placed in the cellar, and found, by equalizing the stores in all, that I did not have to feed that fall. From a trial of this amount for ten different winters, and not having a single colony starve or require feeding before April first, I lately let all colonies go into winter quarters that have 12 and 18 lbs. respectively, and feed all that are short in the spring where necessary, but so far have had to feed but very few at all.

But we will suppose that our colonies have been neglected in the fall from a lack of knowledge of just how many pounds each colony

should have, or from sickness or a pressure of business, how are we to guard against the bees starving? As I object to feeding bees during the winter months unless absolutely obliged to to keep them from starving, I adopt this plan along the line of "guarding."

On some mild day when it thaws a little, without the sun shining (can see best on a cloudy day), go over all the colonies outdoors by removing what you have over the quilt or cloth covering to the frames, and then gently roll this covering up till you come to the cluster of bees, when you will carefully note the amount of sealed honey you can see not covered with bees. We will say it is about the first of February when you do this. If you find plenty of sealed honey along the top-bars of the frames, you can set that colony down as having enough till April. If plenty in half the combs, then it is good till March. If very little, then it should be looked after in two weeks; and if none at all, it should be fed at once. All not needing feeding at once should be left with the hopes that a day warm enough for the bees to fly may occur, when all needing attention should be attended to; but should no such day occur, then they should be attended to before they starve, no matter what the weather.

Well, how shall we feed at this time of year? My way has been to take frames of honey from those in which I see much sealed honey, and give to those about to starve, taking out the outside combs of honey on any day when I could best do so, and putting division-boards in their places. I now place these combs of honey in a warm room for four or five hours till they get thoroughly warmed through, when I go to the destitute colony, take out one or two empty combs on the outside, divide the frames near the center of the cluster of bees, using smoke to keep them from flying, and set in the warmed combs. In this way any apiary which was not in nearly a starving condition in the fall can be brought through till we can feed in the spring. If the colonies are in the cellar, and are where the combs can be got at, they can be looked after in the same way. In the spring the feeding is done with feeders in the regulation manner, but feeding with any thing but combs of sealed honey during the winter months is very unsatisfactory, as a rule.

AN INVESTMENT THAT PAID.

Early last spring it was my good fortune to receive an offer from a party living about ten miles from here, to sell me her entire outfit of bees, hives, tools, etc., for \$40. I went to see the "outfit," and found fifteen colonies of bees,

pretty fair Italians, an extractor, two honey-knives, Bingham smoker, several hundred sections, and about 250 brood-combs, together with nearly 100 old hives that were fit for nothing but kindling-wood. The trip resulted in my accepting the offer, providing they would deliver the whole lot at my place, which they did. During the season they threw off several new swarms, only two of which I secured, the rest going off, owing to my absence from home. They stored 500 lbs. of honey, which I sold at an average price of fifteen cents per pound. From the old hives, musty and broken combs, I secured 75 pounds of wax, which I sold at 24 cts. per pound. I transferred them from the old Quinby frames to the new Hoffman, and in the two-story chaff hives. In preparing them for winter I doubled them up and now have 12 colonies in fine condition; enough kindling-wood for the winter; 100 brood-combs, Quinby size; 500 pounds of honey at 14 cts. per pound, \$70; 75 pounds of wax at 24 cts., \$18; total, \$88.

First investment, \$40; new hives, \$18. Balance on hand, notwithstanding the "bad season and locality," the pleasure and experience, \$29.90.

VAN E. FREEMAN.

Joilet, Ill., Jan. 5.

THE READING OF FOREIGN BEE-PAPERS AT THE CONVENTION; WHAT THE EDITOR OF THE "BIENZENZEITUNG" THINKS ABOUT IT.

In regard to the reading of the foreign papers at your St. Joseph convention, I am of the opinion that Mr. Hutchinson, in his *Review*, is somewhat astray in his position. Mr. Abbott, I think, sees the matter from the right standpoint. I would not have written my article, to be published only in your bee-papers, without payment. Reading my paper in a more condensed manner would have made it worthless. I wrote it as an honorary member of your association, honoring your association and not myself the least. What my friend Frank Benton has said in regard to the invention of the movable-comb hive by Dzierzon, I appreciate. But I have not expressed myself in the right way. I should have said: "Dzierzon invented (as Langstroth in America) the only first *practicable* movable-comb hive—a hive that could be used better than any other invention before, and therefore they were starting a new era."

I have read GLEANINGS with much pleasure, and not the least the Notes of Travel by your father.

C. J. GRAVENHORST.

Wilsnack, Germany, Jan. 2, 1895.

HONEY CANDYING BEFORE COLD WEATHER, AND WHY.

I wonder if you have had an experience like mine. This year, when I extracted in September, combs that were built and filled in August contained many cells of candied honey, just as taken from the hive; and all extracted thickened soon after, before any cold weather came.

What is the probable cause? No syrup was fed till after that time. C. H. LUTSON.

Bridgewater, Mass., Dec. 20.

[Honey from ordinary sources does not candy before cold weather; but certain kinds will granulate very shortly after being put in the combs. The fact that the honey was gathered in August (after the usual flow from basswood and clover) shows that it must have been from some unusual source.—ED.]

WERE QUEEN-EXCLUDERS USED IN THOSE TWO AND THREE STORY HIVES?

I read in GLEANINGS for Nov. 15, 1894, where they tell of those big honey-yields in two and three story hives. The question in my mind is, did they let the queen have the run of the whole hive, or did they use a queen-excluder? Please tell me, is it best to use a queen-excluder for extracted honey? FRED CARD.

Burns, Mich., Dec. 15.

[I can hardly answer in the case of the honey-yields in question; but I should *suppose* that, in most localities, the excluders would be put on top of the second story. In localities less favored it would doubtless have to be put on the first story. The strength of the honey-flow would have to decide the matter largely.—ED.]

THE CROSSES OF FIVE-BANDED BEES.

I see on page 23, GLEANINGS for Jan. 1st, that the editor has something to say in regard to the crossing of five-banded bees with blacks. My experience and his are not alike, as I have never yet seen a five-banded queen mated with a black drone make all yellow bees. On the contrary, they *always* make some black bees, the same as any other hybrid queen or mismatched queen. Now, a five-banded queen can mate to a three-banded drone or to a hybrid, or to any drone whose mother has any yellow about her, and, likely, she will not make any black bees. My experience along this line is, that any yellow queen, it matters not what stock she is, will make some black bees, or nearly so, if she is mated with a pure black drone. I was of the same opinion as Ernest till I thoroughly tested this matter, and now I feel convinced that, when the bees of a five-banded queen show no black bees, she has mated to a drone that had some yellow blood too.

I have asked the opinions of two or three of our most extensive breeders of five-banded queens, and they take sides with me. I think that, when a five-banded queen mates with an impure drone, her bees as a rule will be cross, as most other hybrids are. Not, will the queens make some black bees? but they will make some of the blackest black bees I ever saw. We had one yard out last year, and thought we were putting them out away from other bees, and we soon found that there were black bees near them, and moved them away out on the prairie, and some of our queens were mated before we found out that blacks were close; and I tell you we had some of the blackest black

bees we ever saw, and the queens were from our best five-banded mothers, and they made bees from pure blacks, as far as color goes, up to five-banded, and the bees were as cross as hornets.

I fail to see where the five-banded bees, crossed with any other race of bees, makes them more cross than other hybrid bees. This I mention as I thought of it.

Now, Ernest, you and I will have to fight it out, and I am going to hold my ground as long as I can honestly; and when I see you are getting the best of it I will give it up; but I must say that I think you are away off on this statement, and do not see where you are going to get out unless you walk backward. As for breeding bees for color alone, I think one should be ashamed to do such a thing, and sell the queens, as such a breeder would soon play out, and at the same time injure his fellow-man. I have come to the belief that queen-breeders should be the most careful of apiarists, as they have the reins of the honey-producer, and may lead him to ruin by breeding from any and all kinds of queens. I tell you, it is a serious thing, as well as a matter of dishonesty, for a queen-breeder to use any thing but the best of queens for mothers. I know that I have got off the track, but I just thought of these things, and made mention of it. I should like to hear from others on this subject.

Beeville, Tex., Jan. 17. JENNIE ATCHLEY.

Friend E. R. Root:—I notice in January 1st GLEANINGS, page 23, an editorial stating that a cross between a queen of five-banded stock and a black drone or a five-banded drone and a black queen will, according to your experience, result in all the bees showing at least three bands, etc. I am quite surprised to hear you say this, as my experience does not coincide with yours. Last season I gave the cross-mating of several different strains of bees a thorough trial; and I find, so far as my experience goes, that a cross like the one you refer to will result in producing bees that show from one to three yellow bands, and quite often there will be bees that are produced in this same colony that are as black as the blackest bees I ever saw. Please bear in mind that I am speaking of a cross between five-banded stock and *pure* (German) black drones. I should be pleased to hear from some other queen-breeder in this line, through GLEANINGS. F. A. LOCKHART.

Beeville, Tex., Jan. 17.

Dear Mr. Editor:—Did your hand tremble a little bit when you wrote that editorial on mismatched five-banded queens in last GLEANINGS? I have had numbers of them mated with black drones in the past four years, and not in one instance have I found one producing all straight three-banded bees. Who told you about that?

Chrisman, Tex.

C. B. BANKSTON.

[See editorials.—ED.]

DON'T fail to read A. I. R.'s hints on shipping comb honey during cold weather, in this issue—see page 107.

Two bee-journals now hail from one State. The *Nebraska Bee-keeper*, in its sixth year, and the *Nebraska Queen*, in its second year.

THE article by the Porters, on bee-escapes, will be read with interest, although it seems to have been written for the editor's private ear.

I HAVE just found out who "M. Dea" is, in the *American Bee Journal*, but I shall not tell who he is. In our next issue we shall have a communication from him in our own columns.

AN excellent portrait of Dr. Miller appears in the last *American Bee Journal*. It shows him as he now looks—not so strong and rugged physically as in former years when he sat for his picture, but not one whit older in spirit.

THE paint-mill referred to in a former editorial is now here. We are experimenting with it, grinding up coarse sugar and honey, but so far I am unable to tell whether the results will be favorable or not. Reports will be given later.

I WONDER how many have a comfortable feeling during these cold days (as we find them up here in the North), in the thought that their bees are put in winter quarters in a condition as nice as they knew how to put them. If the winter continues as it has been for the last month or so, it will be a severe one on bees not properly provided for.

I HAVE learned with much regret that Mr. C. E. Parks, Secretary of the G. B. Lewis Co., of Watertown, Wis., and senior member of that firm, is dangerously sick in Florida. Mr. Parks is a man who is well known, not only to the trade, but to the general bee-keeping world, and I am sure I voice the feeling of all in hoping for his speedy recovery.

WITHOUT a single exception, I believe, all the queen-breeders have held up their hands, signifying their purpose to destroy the first case of bee-paralysis as soon as it shall be discovered in their yards. This policy, I feel sure, if adhered to, will stamp the disease out of existence; but if we get the idea in our heads that such extreme measures are not necessary, no such favorable issue may be expected.

I LEARN by the *American Bee Journal* that there is a possibility of Hon. Eugene Secor becoming Governor of the State of Iowa. Good!

I know nothing about his politics; but I would vote for him (if I could) though he were nominated by the Democrats, Republicans, Prohibitionists, or Populists. He is a thoroughly good man in more ways than one. It is this kind of men we want in public office, irrespective of party lines.

I FIND we are again obliged to leave over a number of good articles. Possibly some of them may never see the light of day through the pages of GLEANINGS; but I shall endeavor to give the best of them, and trim down others to the point of solid meat. I might mention here, that one of the most interesting articles we have ever published on bee-paralysis will appear in our next issue, from the pen of that careful and laborious worker, Ph. J. Baldensperger, of Nice, France.

THE story is going the rounds (see the *American Bee Journal*) that Dr. C. C. Miller read an essay at the Illinois Bar-keepers' convention. It would be a "rough one" on the doctor (and probably a good deal rougher on the convention if the doctor had it to do) did we not know how easy it is for a printer to mistake "Bar-keepers" instead of "Bee-keepers," from ordinary handwriting. Or perhaps the mistake was in the telegram, for the printer would hardly make the mistake twice in the same item. Yes, such conventions need a little of Dr. Miller's salt. I hope the doctor's past record will enable him to live down such a report.

THE following sad news is just received from our brother-editor of the *American Bee Journal*, and will explain itself:

A beautiful baby girl came to the home of the editor of the *American Bee Journal* last Friday evening—Jan. 18; but it stayed only a few hours. Of course, there are sorrowing hearts, for its mother and I had hoped so much that when the baby came it might stay with us, and be a great joy and blessing to our home. But, although 'twas hard to give up, we bow submissively to the will of Him "who giveth, and who taketh away."

Mrs. York is doing fully as well as could be expected under the circumstances, I am thankful to be able to say.

Bro. York has our sincere sympathy. These little people, as I know by experience, bring a world of sunshine to the home. I do not know what it is to have that sunshine taken away, for the kind Father has spared me that pang.

IN the department of Kind Words will be found a few reports of the successful mailing of queens to Australia and New Zealand. We have other reports that we do not publish, where the queens went through dead; but as nearly half of the queens went through alive, we feel greatly encouraged, and are in hopes that we shall be able to master the problem after all. The whole secret rests in getting the

candy just right. The candy we last used was made of coarse granulated sugar and honey, with a very little of the pulverized to stiffen the dough. Among those where the queen went through dead, the cause was evidently starvation. The honey had all been taken out between the granules of sugar, and the dry particles of the latter were no better than so much sand.

THOSE CROSSES OF FIVE-BANDERS.

In another column will be found a reply by Mrs. Jennie Atchley and F. A. Lockhart, to the editorial on page 23, to the effect that a cross between a black drone and a five-banded Italian queen does not necessarily show one and two banded bees, but that such bees show all the characteristics of ordinary hybrids, with the exception of color. Mrs. Atchley's experience and that of Mr. Lockhart seem to be diametrically opposite to ours. As she says, let us hear from others on this point. It is only by getting testimony from quite a number that we can form a really decided opinion on this question.

As to my own statements on page 23, I have just been out to ask our apiarist if I had made any mistake. He says not. He is very positive that some of our five-banders, while showing good color, were crossed with hybrids, because their progeny is so fearfully cross. We obtained five-banders from a number of breeders; but as not all of them are cross, I can not say that Mrs. Atchley's bees that we received showed any bad traits. Indeed, so far as I have been able to trace them they were gentle and beautiful, and in several instances were energetic and good workers. As Mrs. Atchley breeds from original Doolittle stock, and, I have reason to believe, takes more than ordinary pains, I assume that her stock is both beautiful and energetic. Mr. Lockhart, I believe, has the same stock.

WIRING BY MEANS OF ELECTRICITY.

We have not said much of late about imbedding wires into foundation by means of electricity. It is not because we considered the plan impracticable, nor because we have found another and better way — nay, far from it. We could scarcely drive our people to imbedding wires with the old-fashioned spur-wheel, so slow and unsatisfactory is it, compared with the neat and rapid method by means of electricity. But perhaps some of you may have forgotten how to construct the battery. Secure three crocks, of not less than a gallon capacity each—larger will make the batteries run longer; and where much imbedding is to be done, crocks of not less than five gallons capacity should be used. For about a cent apiece you can get electric-light carbons at the nearest electric-light station—just such carbons as are used for arc lights. You will need, for

each cell of your battery — that is, for each crock, three long carbons or six short ones. Now, for each crock secure a square board of inch stuff, to cover it. Describe a circle on one of the boards, the circumference of which should be about two inches smaller than the inside diameter of the crock. On the line of this circle bore six holes equally distant, just large enough to receive the carbons. Wire these carbons all together by running a naked copper wire around each carbon a couple of times and then pass it on to its neighbor. Proceed thus with each board. In the center of each circle bore a hole large enough to receive a rod of zinc, the size and length of which is immaterial. If you can not get rods, take sheet zinc and roll it up to about an inch in diameter, and as long as the carbons. Solder a wire to each zinc. The wiring to each cell or crock should be so arranged that the zinc of one battery will be attached by its wire connection to the carbons of the other battery, and so on until you have one free end of the wire from the carbons of one cell, and one free end from the zinc of another crock—the other cell being connected with the other two. These two free ends are to be attached with spring clips, in such a way that they (the clips) engage, or come in contact with the two ends of the wire running through the frame to be filled with foundation. Now, then, before you proceed to work you will need to throw into each crock, say for the three-gallon size, a couple of pounds of bichromate-of-potash crystals. Fill the crock to within $1\frac{1}{2}$ inches of the top, with hot water. Allow it to stand three or four hours, and then pour about a gill of sulphuric acid into each crock; stir; insert the zinc and carbon element, and you are ready for business.

We have experimented with almost every form of galvanic battery that we could learn or read of; but none gave anywhere near such satisfactory results, for the money, as the one just described. If you do not reckon your time at night and mornings, the whole outfit ought not to cost you more than 75 cts., including the chemicals and all.

One charge for the five-gallon size ought to imbed about 1000 frames; but after you have put in about 200 frames you will need to let the battery "rest," i.e., recuperate itself, which it will do in about three or four hours; then you can imbed a couple of hundred more. The activity of the battery may be greatly assisted by stirring the solution occasionally while working it.

We used this form of battery until last season. During the fall, one of our young men of an electrical turn of mind constructed for us a small dynamo, which furnishes a current both for a storage battery which runs the phonograph, and for imbedding foundation. All we have to do is to throw on the belt, and the current is ready at any moment. Of course,

this arrangement is very much superior to the battery, but its cost is twenty or thirty times as much.

THE DOVETAILED OR LOCK-CORNER JOINT IN BEE-HIVES; IS IT A FAULTY CONSTRUCTION?

In the *American Bee Journal*, an interesting series of articles is being written by Mr. Emerson T. Abbott, under the caption, "Production of Comb Honey." In the second article, in the *Journal* for Jan. 24, in referring to the right number of frames for a hive, he shows a decided preference for the eight-frame. Among other things, he says that such a size of hive does away with the necessity of contracting the brood-chamber at any time, and this, he adds, saves the expense of division-boards and contracting. So far we agree. In discussing "the methods of putting hives together," there are some of his points with which I do not agree. "I have been led," he writes, "to wonder a great many times why the so-called dovetailed method has had such a run, as there seems to be some serious objections to it." As one of these objections, he thinks it has been wrongly named, and then proceeds to define the true dovetail. Surely a wrong name is not an objection to the thing itself. Regarding the name, I would say this was originally adopted because it is a term better understood by bee-keepers who have long been used to the same adjective when applied to four-piece sections. Of course, the same objection would apply to the sections. We have, in fact, all along, in referring to the hive in question, called it *both* dovetailed and lock corner; and our 1895 catalog, now ready to be mailed, distinctly refers to it as the dovetailed, or, "more properly speaking, the lock corner."

Mr. Abbott further gives it as his opinion that this joint has nothing about it which renders it superior to the ordinary halved plan, because, he says, "it adds neither strength nor lightness;" and, further, that "it is much harder to set the hives up square, as one has to be very careful in nailing them."

These objections hardly apply to hives of our manufacture—at least, those from our present automatic machinery. And on looking up our records I find that Mr. Abbott has never had any hives of us, of the dovetailed pattern, and I therefore wonder what sort of dovetailed hives he must have had experience with. If he could spend half an hour in our establishment, I'll bet a cooky we could convince him, without a question, that *our* dovetailed or lock-corner joint is far stronger than any halved hive-joint, because *actual tests*, over and over again, have proved it in our shop. By the halving plan the boards bite on each other only half way; by the lock-corner plan the boards bite on to each other the whole way; and added to this is the friction of the fingers, as it were, hugging against each other. By the halved plan, the

strength of the corner depends entirely on the nails; but not so in the lock corner.

I have yet to see a dovetailed hive, when properly nailed, gap at the corners through the influence of the weather, for it is next to impossible; but when the boards are put together by any other plan, a very large percentage (I think I should be safe in saying 50 per cent), after three or four years' time, will show a slight gap, owing to the effects of the weather. In my travels among bee-keepers I have made this a particular point of observation. Moreover, with the bee-keepers in Colorado, California, and in other places where they have those hot winds and a glaring sun, nothing seems to stand so well as the lock corner. These are facts, as I happen to know. Again, we have an unpainted hive of the dovetailed pattern in our yard, that has been exposed to the weather for six years. It is as good as new, so far as the corners are concerned. It shows not the slightest trace of rotting along the notches. There is still another consideration: Dovetailed or lock-corner hives save freight, because four cleats of wood, an inch square, will hold securely 20 sides or ends of the hive, without any additional crating. By the use of our automatic machinery, the expense is very trifling; and this is more than made up by the great saving in crating, in lumber, and time of putting up the hives. It follows, therefore, that, by dovetailing, we save expense to the purchaser.

Mr. Abbott does not like the Hoffman frames. I do not know how much he has tried them; but on this point I recognize that there may be an honest difference of opinion, and in view of this we have for several years back (as we do this year) given our customers the option of a loose unspaced hanging frame.

THE DIFFERENCE BETWEEN FAULT-FINDING AND KINDLY CRITICISM.

I admire the courage of Mr. Abbott's convictions, for I believe that he is honest in them; and I admire, too, that quality in his writings that speaks out plainly, even when they run counter to the views of some of his friends. Indeed, I know he has a very high and warm regard for all the folks here at the Home of the Honey-bees, although he does not see some things as we do. We can always accept the criticisms of friends, and take them in the spirit in which they are written. We all prefer outspokenness far more than outward palaver to the face, and behind the back a dagger-thrust. We here at Medina welcome criticisms that are given in the spirit of kindness, and for the purpose of getting at the truth, and for correcting error; but we ignore those that are manifestly given for the purpose of unloading some pent-up feelings of animosity on the part of those who are constantly *seeking* something with which to find fault. There is a difference—yes, a wide one—between *fault-finding* and kindly criticism.

ON THE WAY TO FLORIDA.

Well, business has been all looked after. I have traveled all over the grounds, from down where the men are cutting ice on the carp-pond, all over the rooms, up stairs and down, through the greenhouses, and given directions for my department of the work until every thing seemed done for my six-weeks' absence as well as it could be done.

After half an hour's ride on the cars we were obliged to wait four hours in the evening at Grafton, O., for the train to Cincinnati. Now, we might have sat during the whole four hours in the waiting-room of the depot; but the stove smoked, the room smelled of something more unpleasant than simply coal smoke, and so I told Constance we would see if we could find a place a little more homelike. Just across the track was a hotel, and a pleasant-faced woman seemed to have charge of it. A nice homelike sitting-room was soon placed at our disposal, with easy-chairs, sofa, and pillows—plenty of lamps, carpets, and all sorts of homelike fixings. She said there would not be any charge for simply waiting there until the train came, and even tried to refuse the coin I offered her. I, however, insisted that she should take it. I told her folks couldn't keep a hotel and supply nice warm furnished rooms for nothing. I soon appropriated the lounge and pillow, for I very much needed a nap after my busy day. After my rest I passed the evening very agreeably with two of my favorite agricultural papers, the *Rural New-Yorker* and *Country Gentleman*.

Let me digress enough to say that I have been continually surprised for some time past to see what an exceedingly valuable paper, for high-pressure gardening as well as farming, the *Rural New-Yorker* continues to be. When they put the price down to only \$1.00 a year, it seemed to me next to impossible that it could be kept up to such a high standard of value; but they have held their own so long that it looks as if they were going to keep it up. Although it is weekly in its visits, it seems to me that single issues are frequently worth the price of the whole year.

I presume the average waiting-rooms in our railroad stations are as comfortable as can be afforded under the circumstances; but whenever there is a hotel near I certainly would willingly pay a quarter for the comforts of a home, for two or three hours.

SOME HINTS ABOUT SHIPPING COMB HONEY.

In Cincinnati we made a very pleasant call on C. F. Muth. He and his son are, as usual, busy in the honey business, and perhaps this is a good time to call attention to the fact that it is risky business trying to ship comb honey during zero weather. Somebody sent friend Muth a shipment, saying that he must have 14 cts. for it. He added, further, that, if any of the honey was broken in transit, Muth should not receive it from the railroad company, but proceed to make them pay damages for said breakage. Now, there are three mistakes in the above method of doing business. In the first place, there should have been some correspondence with Muth before shipping him honey; while in fact, as I understood it, there was none. Muth advertised, as it seems, to pay 14 cts. for first-class white-clover honey; but none of this shipment was first-class, and a consider-

able portion of it was really third or fourth class. Again, Muth isn't in the commission business. He buys outright; therefore it was out of the question to tell him, after it was shipped, that he could not have it for less than 14 cts. Third, no one can make a railroad company pay for honey broken in transit, especially when shipped in zero weather, unless it can be shown that the damage is in consequence of bad handling, and not through any fault of the shipper. Of course, friend Muth could have left the honey in the hands of the railroad company; in fact, I do not know but he renders himself liable in taking it from the depot; but quite a little of it was in such shape that it would have been a total loss if Muth had not taken it, put it in stone crocks, and awaited instructions from the shipper. He told me he would willingly pay the freight and ship it all back to get out of a bad job, if the shipper would accept it.

One reason why it broke out of the sections was that the honey was not securely fastened in by the bees all around. A careful study of the directions for managing, in our bee-journal, would have led the producer to remedy this matter. In fact, very much of the trouble in shipping honey has been on account of lack of attention in this one respect—getting the bees to fasten the honey securely to the wood of the sections clear around. I fear a good many bee-keepers do not understand this, or may be they have never seen a crop of strictly first-class comb honey.

While in Cincinnati we were kindly entertained by the Rev. Norman Plass, former pastor of our church in Medina. He now has charge of the Vine St. Congregational Church, Cincinnati. I was much interested in looking through the church and various rooms for the Sunday-school, Endeavor Society, and other meetings of the young people, and I want to tell you about his

SUNDAY-SCHOOL THERMOMETER.

It caught my eye as soon as I looked into the Sunday-school room, because it seemed to be some sort of scientific instrument. It is simply a piece of wood, in shape, and lettered and graduated similar to a common thermometer-scale, only larger. It is a piece of board perhaps four feet long. Through the center of the board lengthwise a groove is cut about where the glass tube would come in a thermometer. Instead of a glass tube, however, it has a large round cord stretched on pulleys, one pulley at each end of the scale. This cord, half its length, is dyed or painted black. The other half is left white. The superintendent, by pulling on the cord at the back of the instrument, runs what appears to be the column of mercury up or down, and this is the record of attendance. The pupils all watch eagerly to see whether the attendance on any Sunday is high or low, the figures running from zero to 250 or 300. (In smaller schools, say of 25 or 50, the scale may be made accordingly.) The secretary, after he has counted up the pupils, makes the thermometer show the number present where all can see it, and the high or low temperature, as you will notice, rests entirely on the efforts of the pupils and teachers. If they want to make the mercury to stand high they must bestir themselves to bring as many as possible. While such an instrument may not indicate exactly the *spiritual* growth of the school, it at least approximates it.

When we opened our eyes in the morning we were in the vicinity of Montgomery, Ala.; and as we turned eastward, toward Jacksonville, the deciduous trees began to give place to beautiful varieties of evergreens, pines, and magnolias, with here and there trees of various kinds

draped with the beautiful Spanish moss. Occasionally, also, we get a glimpse of the palmetto, or *Lantana*. Cotton-fields are everywhere; but, owing to the disastrous drouth of last season, a good deal of it was hardly worth gathering. This, in connection with the low price of cotton, might well make our Southern friends feel poor and discouraged. As we look out of the car-window, beautiful little evergreens, less than a foot high, and from that up, greet us at every turn; also a beautiful undergrowth, something in the line of rhododendrons or laurels. All these, with occasional glimpses of the different-colored earth, make up a view varied and interesting. I asked the porter if this red earth was not sometimes used for making paint.

"Oh, yes!" he replied; "and one could get enough of it through Alabama and Georgia to 'paint red' the whole wide world."

In this region, cellars seem to be unknown. The houses are set up on blocks or brick piers, so that the wind can blow clear through underneath. Well, perhaps they have no need of cellars to keep things from freezing; but I am sure I should want a cellar in which to keep things cool, and to keep potatoes, apples, etc., from wilting. Another thing, a cellar is perhaps more convenient where room is scarce, and a basement can be made without any expense for roofing. Out in the country most of the buildings, especially the humble ones, are entirely destitute of windows. The only way they have of getting light is to leave the doors wide open; and even on this 17th day of January, in the middle of the winter, the doors are open everywhere. May not this fact of abundant ventilation account for the claim so often made, that, in many parts of Alabama and Georgia, people never die of consumption? that is, they never have it unless they contract it somewhere else. The chimneys are invariably built on the outside of the cheap houses in this country.

For some time I was puzzled to know the purpose of a small light ladder that stood near the chimney. I finally decided that it was to afford access to the loft. When it is time to put the children to bed, all that you have to do is to go outside and climb up the ladder, and this gives more room inside.

PLANTING ON HILLSIDES TO PREVENT WASHING.

I am delighted to find that the corn, cotton, and almost every other crop, is planted on uneven ground, so that the furrows curve around the hillside instead of straight up and down. This is to prevent the terrible washing and cutting that occurs when the water is allowed to go straight down hill. The plan is exactly that recommended by friend Day, in the tomato-book; and in some places we see, every little way down the decline, a deeper furrow or ditch to take away the surplus water before it can accumulate and break over the furrows. Where the crop is clear over the top of the hill, the furrows circle right around the hill-top. In fact, wherever the ground is at all rolling we see these curved furrows left by the cultivator. Where this precaution is not taken, the fields are cut up and ruined. Now, this running the furrows across the hillsides has a value aside from preventing washing. During seasons of excessive wetness it takes the water off before it can be detrimental to the growing crops. It also enables the ground to dry off quickly, so that cultivating may go on speedily, and even where clay soils have been most thoroughly underdrained (the underdrains, of course, running straight up and down the hills), these surface-furrows have a great value.

THE ROSIN AND TURPENTINE FORESTS NEAR THE LINE BETWEEN ALABAMA AND GEORGIA.

I should judge we must now be in the heart of this industry, from the number of barked trees. The bark has been scraped off to get the rosin. As nearly as we can gather from looking out of the car-window, the rosin oozes out like gum from peach-trees where the bark has been removed. When sufficient has accumulated they evidently scrape it off by some means. We have not seen them doing it yet; but we see barrels and barrels of rosin at every depot; and along at the houses the people are boiling something out of doors in iron pots. Now, we can't discover whether they are cooking a dinner or boiling rosin. Will somebody from this region tell us about it? In some of the pine forests we see notches cut in the trees so as to make cavities; and I judge they dip the turpentine out of these cavities. Now, do both turpentine and rosin come from the same kind of pines? Will somebody straighten us out in regard to this industry? There are miles and miles of these scarified trees, the rosin on the trunks making them look white, like some immense cemetery.

All through Georgia we have been struck by the beauty of the pine forests. In some places the trees are as straight as arrows, about as close as they can grow, and of wonderful beauty and regularity. No wonder Georgia has been celebrated for its cypress and pine timber. But it seems to me that a good deal of it is going to waste shamefully. The trees are girdled, simply that they may plant corn and cotton between them, and then are allowed to stand until they rot and tumble down—for the reason, I suppose, that it is less trouble to let them stand than to have them down in the way of cultivation. If these beautiful trees are of no value now, they certainly will be in the near future. Some of the finest timber we have seen is in the vicinity of Bainbridge, on the Flint River.

KIEFFER PEARS.

Georgia has of late been coming to the front grandly in the line of fruit-growing, especially peaches and pears. All about Thomasville and beyond we see acres of large pear-orchards, of wonderful beauty and luxuriance. I judge them, by the looks, to be the Kieffer.

LETTER TO HUBER.

We have just passed a station, Huber, which is called "Dixie." You don't remember any thing about the old war-time song called "Dixie Land;" but I think mamma can tell you something about it. Here is a verse:

In Dixie Land, where I was born,
Early on one frosty morn,
Look away, look away,
Look away to Dixie Land!

Chorus—

Den take me back to Dixie,
Ho-ray! ho-ray!
In Dixie Land I'll take my stand
To live and die in Dixie;
Ho-ray! ho-ray!
To live and die in Dixie.

Well, Huber, what do you think of that? I do not wonder the Southern people were so enthusiastic about Dixie Land, especially if it was as beautiful then as it is now. I tell you, Dixie Land is just what you'd call "slick." The rays of the afternoon sun, as they strike the brilliant green of the pines, palmettoes, and live-oaks, give a view that is grand indeed; and the water along the side of the track makes a reflection like a great looking-glass. The water is so clear and dark and still, in fact, that the

reflection is almost equal to the reality.* Taking it all in all, I am sure you would give your verdict in your most emphatic way, that Dixie Land is "just slick." Constance says the luxuriant tropical foliage is beautiful with all the shades of the rainbow; but you see I am a trifle color-blind, and don't see much except the brilliant shades of green. It is not only the vegetation that is radiant with brilliant colors; but even the *ground itself* here in Dixie Land shines out with many tints, running all the way from white and gray and yellow sand to the brightest orange and vermillion. You see, it is this funny, sandy soil. In some places the roads look as if they were sprinkled with salt. It is only the patches of white sand sprinkled in with the rest. Wherever we see this white sand, especially where it is trodden down hard by the bare feet of the little colored boys and girls, I tell you the wheeling would be "just slick" too if I could get out to try it. And, by the way, these little colored people, with their white frocks contrasting with their shining black faces, furnish another bright element in the picture. There are free schools for these little colored people, and I rather think that is one reason why their faces look so bright and happy. It is summer time down here, even if it is the middle of January, and these children are not only barefooted, but, for the most part, barelegged. As we go past on the cars everybody is either standing in the door or outside the door.

While passing through Kentucky a sick man came on board the train with his family. His wife informed me that he was a broken down clergyman, suffering from nervous prostration, on his way to Florida. I did not talk with him until we were near Jacksonville, as I feared it might aggravate his trouble to see strangers. An accident, however, opened the way; and when I introduced myself he replied something as follows:

"My dear sir, I am delighted to make your acquaintance; for, to tell the truth, I have gotten acquainted with you already from overhearing you dictate to the young lady. I could not well help listening; and the more I listened, the better I felt satisfied that it was intended for the great public ear. I heard you tell about the smell in the waiting-room that was something worse than coal-gas, and I was very much interested in the Sunday-school thermometer."

We exchanged experiences, and I believe I gave him faith and hope, besides some ideas of my own in regard to "doctoring without medicine." His wife's aunt accompanied them, and I was greatly interested in her because she was born blind. After hearing something of her from Constance I introduced myself, and she invited me to sit down by her side. She can not tell the difference between the broadest daylight and the darkest midnight; has no perception at all of shade and shadow. Of course, she can feel the heat of the sun, and is unusually sensitive to all these influences. She has no idea of color or brightness excepting what is told her. Said I, "My good friend, if you succeed in being happy and thankful while you are for ever shut out from sight and light, how ill it becomes us to complain of our lot, especially when this great affliction is no fault, in any sense, of your own. Some in your condition might complain, and with quite a show of reason, that the great Father above is unfair. You remember, of course, the disciples asking the Savior, 'Whose fault is it, this man's or his parents', that he was born blind?'"

*Cousin Louise has told me since that it is the roots of the palmetto that dye the clear water black, or dark colored, so that it reflects the landscape almost like a polished steel mirror.

She caught hold of the idea quickly, and replied, "Oh, yes! and I have often thought of his answer, that 'it was through no fault of the man or his parents, but that the will of God might be made manifest.'"

Then I suggested that the great lesson to her was to have faith to believe that God had some plan or purpose, even in her case, to manifest to the children of men his wondrous providences. I shall always remember how that expressive face, even despite the sightless eyes, brightened up as it seemed to look up and grasp for faith. As I dictate, the words come into my mind:

My faith looks up to thee,

Thou Lamb of Calvary, Savior divine.

I suggested that her darkness was not to be compared with that of those who, "having eyes, see not; and having ears, hear not," and she at once replied that she by far preferred her lot in life to the darkness of sin and a guilty conscience, and without the light of the gospel.

She had heard of Helen Keller, and I promised to send her the book telling all about Helen's wonderful experience. She said her niece's children were quite ready and willing to read to her. If any of you wish to address her, send in care of G. W. Yancey, Ocoee, Orange Co., Fla. Perhaps I may mention that her mother was exposed to the measles, and took it shortly before her birth, and thus a human life of darkness.

As I sit out on the veranda which opens out from my pretty little bedroom in Jacksonville, Fla., the bees are humming in the soft-maple blossoms that spread out almost within my reach. I sat here in my shirtsleeves, and penciled a card to my old mother before 10 o'clock in the morning. When I left Medina a good many urged me to leave my wheel at home, as I could never make a bit of use of it in Florida. Even Ernest (and I am surprised at him) suggested that it would be more trouble than it would be worth, from all the reports he could gather. But as soon as my wheel was uncrated I took it to carry my postal to the letter-box, and found out by somebody that there was a brick pavement a little way off. I reached there by means of the sidewalks. Then I ran up past the waterworks, where three artesian wells were pouring forth beautiful water, looking much like those wells I described on my Missouri trip.

About this time I struck a shell road, and, under the inspiration of this beautiful track, the exhilaration of the springlike air, and encouraged by the chirping of the tree-toads, I declared to myself that I would follow that shell road wherever it wended, even if it took me twenty miles or more. Why, I never saw a finer wheel-track in my life. The graveled pikes in Western Ohio are in no respect better—hardly equal—because they are not on such a dead level. One can ride miles without touching the handle-bar at all.

After a trip of about five miles, curving around through beautiful piny woods, palmettoes, magnolias, and various glossy-colored underbrush, I came to the Jacksonville cemetery. As it was near the dinner-hour, after a hasty trip through the grounds I sped me home again, and made the trip of five miles in just 17½ minutes, besides getting lost; and I might have been considerably longer had not Constance called to me from the aforesaid balcony above, asking me why I was spinning right *past* the house where I lived. Now, others may say what they please; but I for one think it pays to take a wheel along on a Florida trip, just for the beautiful rides around Jacksonville, even if there shouldn't be any thing like it in any of

the other towns. When I reached the end of the shell road, at one point I tried my hand at wheeling through Florida sand. I was obliged to give it up; but a lady informed me that the sand *here* was not a circumstance to what I should find in South Florida. On a pinch I could make better speed than to walk; but it was pretty hard work, if followed any length of time.

THE ARTESIAN WELLS OF JACKSONVILLE.

As I started out early one morning to make explorations I noticed a place for watering horses; and as the water came out of the iron pipe it seemed to be steaming. On touching the pipe I found it quite warm. The water, too, seemed to be toward 70°. Later in the day I visited the artesian wells. There are three of them. The two first that were drilled were put down to a depth of 600 or 700 feet. The last one, which gives the largest volume of water, is down to something over 1000 feet. The constant temperature of the first two is about 70°, while the deepest is a little over 80°. Now this, you see, is warmer than we need our living-rooms; and, in fact, warm enough for tropical plants in a greenhouse. But no one has ever yet, that I know of, made use of this great storehouse of heat, to warm buildings, to grow plants, or any thing of this sort. Why, I should regard it as a mine of wealth for the purpose of giving an absolutely even temperature; and, by the way, I have not as yet found any thing around Jacksonville, in the way of market-gardening or growing vegetables, worth mentioning. There is just one little dilapidated greenhouse, and this is used only for flowers. Why don't people make gardens where the bees are buzzing in the soft maples, and the temperature seems to be just exactly right for many hardy vegetables? I said to the engineer of the waterworks, "Why, where does this water come from? It's away up above the ocean, and away above the St. John's River. Is there no elevated body of water anywhere around that could furnish a supply of water for these wells that have been running for so many years?"

"Well, sir, this is a secret that no man has ever yet found out. There is no elevated body of water, and, for that matter, scarcely any elevated land anywhere near. There have been conjectures by scientific men that this water stratum extends clear up to the Cumberland Mountains; but this, of course, is mere guesswork."

This water as it comes from the wells is like that at Clinton, Mo.—sulphurous; and the bottom of the reservoirs and overflow streams is decorated with all the colors of the rainbow. I supposed it was from the minerals it contained; but my friend the engineer explained: "Not minerals, Mr. Root, for this is almost absolutely pure water. These beautiful colors are the result of a species of moss, or algæ, and this vegetable growth takes place only where the water is exposed to the sunlight. See here; we have one reservoir roofed over and bricked up so as to make it dark like a cellar. There is none of this growth in this reservoir at all; but where it is exposed to the full sunlight it grows very rapidly. It commences on the stone or sand at the bottom, where the sun can strike, and gradually breaks loose and floats away, the warm temperature, 70 or 80°, greatly facilitating this vegetable growth. Here at the wells the water has a strong, sulphurous taste;

but after exposing it to the air as it pours over through the fountains, this odor at last disappears. You will notice, when drawn from the hydrants in the city, it seems to be pure water, with scarcely any taste of the sulphur at all." Now, you see we have at least a partial explanation of the wonderful mossy covering of the ponds of spring water in Castalia, Erie Co., O.; and here is a solution, too, of the cause of the mossy growth and covering surrounding the watering-troughs and streams from springs throughout our land. Put a box or tub around your spring, either of stone, brick, or wood, then have a hinged cover over it to lift up, and you won't have any of this slimy moss or scum. All you have to do is to keep away the sunlight, and it can't grow. One of the agricultural papers recently stated that whitewashing a watering-trough, or even placing a lump of lime in the water, would keep away the moss. You see the idea is, that the moss is a vegetable growth, and propagates itself, and grows in the spring water, simply because this water furnishes the desired temperature, especially where it flows out into the sunlight. And this slimy moss, then, really is not found at all, nor even the *elements* that go to make up its growth, in the water itself, as it comes from the ground or rocks. I am glad to know this, for I had a sort of notion that the water was not pure where this sort of deposit was all along the outlets of the spring. And, by the way, may not this mossy substance be utilized? At Castalia great quantities of snails breed in it as it floats on the surface of the still water in the ponds; and ducks may be reared in immense quantities, getting almost their entire sustenance from the snails on the water. Peter Henderson speaks of cocoanut fiber being a valuable material for mulch, and for incorporating with certain soils in raising crops. I am of the opinion that this mossy substance floating on the ponds would be still more valuable. In Castalia there was not only wagonloads but carloads of it, which I presume the people would be glad to get rid of. If thrown upon the banks until dried out it certainly would be a splendid absorbent to be used in stables, making our ponds and streams look more tidy besides.

JACKSONVILLE.

This is a very pretty city of nearly 30,000 inhabitants, and is the largest in the State. At the present time there is a very general activity all over the place in putting in good substantial street pavements. The cedar-block pavements are being removed, and either vitrified brick or cement put in its place. The cement pavement is made of material found only about 25 miles away, and brought in by boats. It seems to be a sort of limy marble; and when mixed with sand it resembles hard putty, and pounds down into material that is something like hard wax. They claim that, when once packed and rolled, it will turn off rain; and I should think that, with some attention to keep it in shape, it might do this.

There are plenty of churches here; and, judging from the sermons we have heard, their ministers are educated and able, and fully up to the times. Their audiences are made up also of people of intelligence and culture. For once in my life I have attended church where the ventilation seemed proper, especially for such a climate. There were very large windows, which were opened so that the church seemed like a great airy veranda; and those who were tempted to stay away from the service because of the enticing air and sunshine out of doors had certainly no reason to call the church close or confining. Endeavor Societies and Sunday-schools also seem to be doing effective work. The city is very quiet and orderly on Sunday.

*Another thing, where does this 80° of heat come from, 1000 feet below the surface? Is it possible this high temperature and the elevation of the water are in some way connected? If the water were forced up by steam, however, would it be possible for the water-pressure to remain so perfectly even, year in and year out?

Places of business were generally closed except the fruit-stands and drugstores. Besides the churches for the white people, those for our colored friends seemed ample and well attended. I never before saw so many *motley dressed* colored boys and girls. These people as a rule seem busy and industrious all through the city.

All around the depot, and on the principal streets, Jacksonville is *indeed* a busy place. In fact, to accommodate business traffic an immense structure, a real viaduct, spans all the railroad tracks, and connects Riverside with the principal streets of the city, leaving the track-yards unobstructed for the railway traffic. On this viaduct one may see crowds of people on foot, with teams and street-cars passing to and fro almost every hour of the day. In our northern cities at the present time we see very little building going on; at least, there are few structures being put up of any considerable size. But here there are not only an immense number of fine dwellings, but a large union depot is under full headway in process of construction. The terrible frost, that has been such a severe setback to many of the great Florida industries, seems to have had little effect in stopping improvements here.

SOMETHING GOOD FROM CANADA.

We notice, by the *Practical Farmer* of Jan. 5, that T. B. Terry has been invited over to the Queen's domains. We make the following extract:

One of the pleasant features of the meeting was a banquet. At 6 P. M. we moved from the hall, where the work was done, to a great room where numerous tables were loaded down with good things to eat, besides being most beautifully decorated with flowers, etc. As I walked through this beautiful spread, at the head of the procession, with the wife of my esteemed friend, President Mills, on my arm, I thought that farmers were certainly most highly honored in Canada; and when it came to drinking (water) to the health of the Queen, I know that I did it as heartily as any one there. About 300 were seated at this feast, and eating and toasts, and speeches and merriment, made $3\frac{1}{4}$ hours pass away very quickly.

Allow me to say the above is tiptop; but here is something of more special interest to bee-keepers, for it concerns the president of the N. A. B. K. A.:

I feel particularly indebted to one of my best friends, Sec. Holtermann, for giving me a chance to see all these things with my own eyes and hear them with my own ears. Somehow we do not get a full idea from reports issued by the Society. They are too modest. T. B. TERRY.

HITCHING-POSTS IN THE MIDDLE OF TOWN.

Inasmuch as I have had my say recently in the matter, it may be best to give the following from the *Massillon Independent*:

MIGHT NOT WORK.

A little reform in the matter of hitching horses in the business center would be gratefully accepted by everybody. It could be accomplished without giving offense to anybody, by the exercise of tact on the part of—say, the police force. A personal request, for instance, to move on to some side street, would in time cause country visitors to accustom themselves to a change of habit, and the business streets would be made much freer for traffic.—*Massillon Independent*.

Replying to the above, the *Wadsworth's O. News* says:

That thing was tried in Belvidere, Ill.; and then the country visitors politely told the city dads that, if they were not allowed to hitch on the principal street, they would go elsewhere to trade.

[To which I wish to add, "Good for the 'country visitors.'" Let the "city dads" have the town all by themselves, after their own fashion, and see how they like it.—A. I. R.]

PINK BEAUTY. (KOSTELETZKYA).

One of the greatest floral novelties of the age. Perfectly hardy, and covered all summer and autumn with beautiful, tender, bright, rosy-pink flowers as large and almost as round as silver dollars. Blooms first year from seed; forms a dense shrubby plant 3 feet high that remains in perfection a lifetime. Grows readily from seed and succeeds everywhere. Seeds, 25c per packet. Plants, 25c each, or 3 for 50c by mail.

GIANT PERENNIAL SWEET PEA.

Flowers 2 inches across; a lovely shade of lilac-blue with feathery markings of deeper blue and a clear white eye. Forms a dense vine 6 to 8 feet high. Blossoms the whole of July and August. Surpasses the finest Clematis. Hardy, growing more beautiful from year to year. Seeds, 15c per packet. Plants, 25c each, three for 50c, by mail.

A Flower Garden for 25c.

To introduce our seeds into thousands of homes, and prove by results their superior quality, we mail ten full-sized packets of Flower Seeds for 25c. These packets contain hundreds of varieties, and with the simplest culture will produce a brilliant display of beautiful flowers all summer and autumn, and plenty for cutting for the house. Also a collection of ten full sized packets of Vegetable Seeds, all fine varieties, for 25c.

All Fully Described in Our

GUIDE TO HORTICULTURE.

A large book of over 150 pages, copiously illustrated and elegantly printed. In it we describe and offer seeds and plants of every thing worthy of cultivation in the way of Vegetables and Flowers, Small and Orchard Fruits, Hardy Flowering Plants, Shrubs and Vines, Roses, Cannas, Gladiolus, Lilies, and other Bulbs, Aquatic Plants, Chrysanthemums, etc., and give full instructions for pruning, care, and culture.

To all who order any of the above the GUIDE is mailed FREE. To those who send TEN CENTS, and say where they saw this advt., we mail a full set of the lovely Variegated-leaved Tuberoses, 3 bulbs of Gladiolus, and the GUIDE.

250 acres of Nursery. 25,000 ft. Greenhouses.

THE LOVETT COMPANY,

Little Silver, - New Jersey.

Notice.

Pacific Coast

Bee-keepers.

We are Northwestern Agents for The A. I. Root Company's supplies, and can make prices that will interest you. Send us a list of your wants, and see if we can not save you money.

POSSON'S SEED STORE,
Portland, Oregon.

The New Craig Seedling Potato.

For full description of this Potato, see page 959 of this journal for Dec. 15, 1894. Prices: 1 lb by mail, postpaid, 25 cts.; ½ peck, by freight or express, \$1.00; 1 peck, \$1.75; ½ bushel, \$3.00; bushel, \$5.00; barrel of 11 pecks, \$12.50. The above prices will hold good as long as our stock lasts. All orders by mail will be filled as soon as received. Orders by express will be shipped at once unless ordered otherwise. All orders for potatoes by freight will be filled April 1, or soon after that time, unless directions are given to ship at an earlier date. In this latter case I do not assume responsibility for loss in freezing; but where it is desirable to ship earlier, and customers have had luck, I expect to help them out so far as I can consistently. In regard to my responsibility I would refer you to A. I. Root. In fact, where it is more convenient you can order potatoes of the A. I. Root Co., instead of sending your orders to me.

GEO. E. CRAIG, Zimmer, Franklin Co., O.

B 4 U Buy Seeds or Plants,

Send for my
Annual Catalog.

It is neatly gotten up; no old stereotyped matter about it; nothing sensational. The Best Varieties **truthfully described and honestly priced.** A. I. Root says, "I believe I have read every catalog you have put out clear through, and I wish all seedsmen would tell us their experience with different varieties as frankly as you do." True Prizetaker onion seed and plants a specialty. Vegetable and small-fruit plants of all kinds, trees, and supplies for gardeners. Send for free catalog at once, or send 10c for catalog, a pkt. of a new smooth very early tomato, a pkt. of the best new lettuce, a pkt. of true Prizetaker onion, and a pkt. of choice flower seeds, **all for 10 cents.**

It won't hurt to

LOOK OVER

My new 60-page catalog for '95 before ordering your hives, etc. Goods and prices are **ALL RIGHT.**

J. M. Jenkins, Wetumpka, Ala.

For Sale or Exchange.

To close out my factory, machinery, and aparian stock of all kinds, I will give purchaser a rare chance. Write me with enclosed stamp for particulars. Must sell or exchange.

Chas. L. Hill, Box 495, Dennison, O.

METAL WHEELS for your WAGONS.

Any size you want. 20 to 56 in high. Tires 1 to 8 in wide—hubs to fit any axle. Saves cost many times in a season to have set of low wheels to fit your wagon for hauling grain, fodder, manure, hogs, &c. No resetting of tires. Call's free Address **EMPIRE MFG. CO., Quincy, Ill.**

FLAT COVERS.

According to the new catalog, the option in hive-covers is between Higginville and ventilated gable. If any prefer the old style flat cover they may have them, if specified in the order. When no specification is made we send Higginville covers on single-wall hives, and telescope covers on chaff hives.

BUSINESS AT THIS DATE.

We are having so much work that we are running on full time, and have been for some time. We are also working the machinery in our wood-working department to its full capacity with a force of forty men and boys. We are turning out our extra polished sections at the rate of a million a month; and we have orders booked, and already shipped since Jan. 1, for over two million. This is somewhat of an indication of how they are appreciated.

CATALOG OF BEE-KEEPERS' SUPPLIES.

We expect that every reader of GLEANINGS will receive a copy of our new 1895 catalog in advance of this number of our journal. We may not have all mailed till a day or two after; but if you have failed to receive a catalog within a week after receiving this, write us for one if you care for it. It may be some time before our catalog of tools, household goods, and specialties, is out; but we will get it out as soon as our multitude of other cares will permit.

FLORIDA BRANCH.

Shipment of the second carload for Florida was deferred on account of the freeze, which materially changed the plans and prospects of many bee keepers there. We expect to ship a second car early this month. If in need of anything in our line, write Mr. A. F. Brown, San Mateo, as soon as possible after reading this item, so that, if he has not in stock what you want, it may come forward in the next carload to go.

SYRACUSE BRANCH.

The bee-keepers of Central and Eastern New York and adjacent territory have shown their appreciation of the convenience of being able to obtain our goods at our catalog prices at Syracuse, where Mr. F. A. Salisbury has had charge for the past three years. The sales have increased each year over the preceding. We shipped to Syracuse last week the first carload for this season, and more will follow as needed.

NORTHWESTERN BRANCH.

We expect soon to ship a carload of goods to our representative at St. Paul, H. G. Acklin, 1024 Miss. St. Any one in that vicinity wanting any thing special will do well to write above address, with order, that your wants may be supplied in this car. There is a good stock of hives on hand at St. Paul—Nos. 1, 1E, 2, 2E, 8-frame; No. 5, 8 and 10 frame, and No. 1E, 10-frame, packed as furnished last year, with flat cover and without nails and brood-frame starters. Mr. Acklin will repack these as per new catalog, if desired, or he will furnish them as they are at the old catalog price, with 5 per cent deducted. This reduction is offered as an inducement to furnish them as now packed, so as to save the trouble of repacking.

ANOTHER BRANCH HOUSE.

As we go to press we are loading a car with a general assortment of supplies destined for No. 10 Vine St., Philadelphia, where Wm. A. Selser will dispense the goods to the bee-keepers of the southeastern quarter of Pennsylvania and south half of New Jersey. The goods will be sold at our catalog prices, and Mr. Selser is supplied with catalogs as well. Mr. S. is an enthusiastic bee-keeper as well as a thorough business man, so that you can depend upon his giving you good service. He will also try to supply the Philadelphia market with honey; and if you have any to dispose of, especially clover honey, communicate with him at above address. He will, no doubt, be able to sell large quantities.

JOHN NEBEL & SON.

We have sold a carload of our supplies the past month to John Nebel & Son, of High Hill, Mo., and have printed for them a supply of catalogs. It was the pleasure of the writer to be entertained at the homes of these genial Missourians on his return from the International Convention at St. Joseph last fall. They have a very pleasant location at High Hill, and have a beautiful stock of bees. They have been prominent as queen-breeders for a number of years, and well deserve the success they have attained in that line.

COLUMBIA PRUNING-SHEARS.

The time for fruit-tree pruning is at hand, and already here in some sections. We have something new in the way of a shear to offer, which is superior in many ways to the old style. The joint between handles and blade is so made as to give the blade a shearing movement, ensuring easy cutting. The blade also cuts in the center of lower jaw, the edge bedding in a hard paper filling. The handles are of malleable iron, smoothly polished. It is a superior tool, which will be appreciated. Price 35c; by mail, 50c.

BEMAN AUTOMATIC OIL-CAN.

Who has not been annoyed by occasionally overflowing a lamp when filling from the ordinary oil-can? If your can is such that you draw the oil from a faucet, have you not been annoyed by the can springing a leak around the faucet? These and other difficulties are overcome by the can shown below.

This is a plain can, with no openings except in the top, and no projections to get bumped and start a leak. The pivots in the side of the three and five gallon sizes, on which they swing, consist of a steel rod running clear through the can, washed and soldered at each end, inside and out.

Manner of Using.—Simply hold the lamp in position on the filling-tube, inserting as far as the tube will go in the lamp, and tilt the can over until the oil runs into the lamp, which will fill to the proper height, and cease flowing automatically. Tilt the can back, raising the lamp at the same time to the first position; then remove the lamp, at the same time tilting the can backward until the oil in the tube runs back into the can, and there will be no drip whatever.

Principle of Construction.—The can is provided with an air-tight screw-cap, which should always be kept turned down tight. The filling tube, or spout, is double, one part connecting with the oil-space, and the other with the air-space of the air-tight can. The oil rising in the lamp to cover the end of the tube, shuts off the air, or vent, and thereby automatically stops the flow.

Three and five gallon sizes are made of galvanized iron, and have swing as shown. If more convenient, the stand can be hung on two hooks on the wall as a bracket, allowing the can to swing just the same. A one-gallon size, of tin, without swing, is also made. Price, 1 gallon, 35 cts.; 3 gallons, \$1.25; 5 gallons, \$1.50.

HONEY COLUMN

CITY MARKETS.

BOSTON.—Honey.—Our market continues without change. Comb honey, 13@14; extracted, 5@6. Pure beeswax is wanted, at good prices. No stock on hand, with some inquiry. E. E. BLAKE & Co.,
Feb. 8. Boston, Mass.

DETROIT.—Honey.—Honey is selling slowly. Best white comb continues to be quoted at 14@15; other grades, 11@13. Considerable in sight. Extracted, 6@7. Beeswax, 26@27; demand good.
M. H. HUNT,
Feb. 8. Bell Branch, Mich.

CLEVELAND.—Honey.—Honey is moving very slowly at about the same prices as quoted in last issue on account of the cold weather. No. 1 white comb, 1-lb. sections, is selling at 14@15; No. 2, 12@13. No. 1 water-white extracted, 6@8. Beeswax, 25@26.
WILLIAMS BROS.,
Feb. 7. 80 & 82 Broadway, Cleveland, O.

ALBANY.—Honey.—Consignments of comb honey are arriving in bad order, due to the extreme cold weather. Clover is selling at 12@13; buckwheat and mixed, 8@10. There has been a good demand for extracted buckwheat, and our large stock is nearly all sold; 5@6c is the ruling price. White will bring 6@7; but the demand is principally for dark.
CHAS. McCULLOCH & Co.,
Feb. 9. Albany, N. Y.

BUFFALO.—Honey.—No material change in honey. Trade is very quiet. Moderate amount of fancy moving off slowly, mostly at 13c. Choice goods, 11@12; commoner grades are exceedingly dull, and hard to move, at irregular prices. Would not advise shipment of honey here at present. Extracted very dull at 5@6.
BATTERSON & Co.,
Feb. 7. Buffalo, N. Y.

CINCINNATI.—Honey.—Demand is slow for all kinds of honey. Comb honey brings 14@16 in the jobbing way for best white. Extracted, 4@7; supply fair. There is a good demand for beeswax at 22@28 for good to choice yellow.
CHAS. F. MUTH & SON,
Feb. 7. Cincinnati, O.

CHICAGO.—Honey.—Owing to extremely cold weather there has been very little comb honey sent out, but our market continues to rule at 14@15 for the best grades of white; dark uncertain at 8@10; a good light amber sells at 12c. Very little trade in extracted honey; prices range from 5@7c, according to quality, color, and flavor, and style of package. Beeswax brings 27@28 for the ordinary run.
R. A. BURNETT & Co.,
Feb. 7. 163 So. Water St., Chicago, Ill.

PHILADELPHIA.—Honey.—Comb honey slow sale, and in poor demand at 11@13. Extracted in good demand and limited supply, at 5@6½. Pure beeswax very scarce, and in good demand at 30c.
WM. A. SELSER,
Feb. 11. 10 Vine St., Philadelphia, Pa.

Closing out balance of my fine extracted basswood honey at 7c f. o. b. Who is not supplied?
ELIAS FOX, Hillsboro, Wis.

ALFALFA HONEY. very white, thick, and rich. Two 60-lb. cans at 7c. Same, partly from cloome (tinted), 6c. Samples, 8c.
OLIVER FOSTER, Las Animas, Col.

We yet have extracted alfalfa at \$7.80 per box of 120 lbs.
AIKIN BROS., Loveland, Colo.

WANTED.—5000 lbs. clear yellow beeswax, at 27c cash; also several tons pure extracted honey that does not contain basswood or buckwheat; also several tons pure extracted white-clover honey, at 10c; send sample and quantity before shipping, to
WM. A. SELSER, 10 Vine St., Philadelphia, Pa.

FOR SALE.—Alfalfa comb honey, snow white, 12c; partly from Cloome, light amber, 11c.
D. S. JENKINS, Las Animas, Col.

CURRENTS **FRED. H. BURDETT,**
CLIFTON, NEW YORK.

Crane Smoker

1895 Pattern.

This excellent smoker was introduced some two years ago, since which time it has worked itself rapidly into popular favor.

Its Distinctive Feature is the Crane Valve, by which the full force of the bellows is secured without waste, and by which also smoke is prevented absolutely from going into the bellows.

The Legs are of Skeleton Malleable Iron, contracted at the feet so as to be out of the way of the fingers in handling, and are secured to the bellows by bolts instead of screws.

The Shield is of Light Corrugated Tin, and bags next to the bellows, thus giving ample protection from heat.

The Cone Top easily tilts back for replenishing the smoker, and is secured by a malleable-iron hinge, the working parts of which are milled so as to insure accurate adjustment to the stove or cup.

As to Fuel, it will burn any thing, including Soft Coal, Stovewood, Planer-shavings; and it makes no difference how much the latter may be crammed down in the cup, there will be the same strong blast as before.

Price, 3½-inch barrel, \$1.85, postpaid; or \$1.50 by fgt. or exp.

The A. I. Root Company,
Medina, Ohio.

J. B. CASE, Port Orange, Fla.

Vol. XXIII.

FEB. 15, 1895.

No. 4.

STRAY STRAWS

FROM DR. C. C. MILLER.

23° BELOW ZERO, Feb. 5—the lowest point up to that date.

THE BEGINNING of the series of articles on extracted honey, by Chas. Dadant, in *A. B. J.*, is something in the line of an historical treat.

THE BRITISH BEE JOURNAL thinks it is not an extravagant estimate to suppose the British Isles could produce annually 5250 lbs. of honey.

AN APIARY of 34 colonies on top of a four-story building in Philadelphia is reported in *A. B. J.* Averaged 50 lbs. per colony in 1892 and 1893.

"DOES IT PAY for the trouble to pack bees in the spring after taking out of the cellar?" is a query in *A. B. J.* Sixteen say no, five say yes, and a few give mixed answers.

THE A. I. ROOT Co. seems to be putting branch houses everywhere. Please give the street and number of the Marengo branch, so I can save freight from Medina.

AT ROCKFORD, ILL., convention, several cases of killing bees by spraying fruit-bloom were reported. One man sprayed his plum-trees while in bloom, and killed 30 colonies of bees.

I THOUGHT Doolittle was a Prohibitionist. But from the way he scatters around sawdust at intervals on the bottom of his bee-cellar, it's evident that he's quite familiar with the ways of the saloon!

"FOUL BROOD" and "compulsory powers" are words seen very frequently in connection in the *British Bee Journal* nowadays, which means they're making strong efforts to have foul-brood laws.

"I FIND NO DIFFICULTY," says J. Martin, in *B. B. J.*, "in retailing over half a ton of extracted honey every season at one shilling per 1-lb. bottle." Think of it! \$250.00 for 1000 lbs. of extracted honey, and the bottles to hold it!

W. STOKES, Balnastraid, Scotland, writes: "I am very successful in wintering. I use an

outer case, giving about two inches between it and the hive. This space I pack with mats made of rye straw, which gives warmth and ventilation."

G. K. HUBBARD reports in *A. B. J.* that in moving his bees by wagon 50 miles he laid "a small, tightly rolled roll of burlap across each end of the frames before nailing fast the covers." That kept the frames in place without other fastening.

IT'S DOUBTFUL if any one overlooks that ad. on p. 112. It won't hurt that chap to "look over" providing he moves cautiously; but a sudden dodge backward might be fatal, for the size of his lip is altogether out of proportion to the allowance of neck.

A NEW DEPARTURE in the way of programs is that of Wisconsin for their winter convention. Not a speaker or essayist is mentioned, but eight thoroughly practical topics are named for discussion, with no hours named. I bet you they'll have a good time.

HERR REEPEN, the *Centralblatt* epitomist, met a box-hive man with 450 lbs. of wax on his wagon who had harvested 6000 lbs. of honey, making him a net income of \$625. Herr Reepen agrees with many others that box hives should still hold a place in the heather regions.

I DON'T KNOW who wrote this beautiful verse, but it's what I wish for all the GLEANINGS family:

Not to be tuneless in old age,
Oh! surely blest his pilgrimage,
Who in his winter's snow
Still sings with note as sweet and clear
As in the morning of the year
When the first violets blow.

WHERE ARE WE AT? GLEANINGS, page 104, talks of voting for men, "irrespective of party." What will become of our country if it comes to that pass that a man isn't ready to sacrifice any thing and every thing for "the good of the party"? Allee samee, I indorse what is said about our Eugene, and add that he's no office Secor.

HERE'S HOW Jas. Poindexter treats colonies that have swarmed, the same having clipped

queens: "The queen is caged and placed under the alighting-board, when the swarm soon returns, and at the end of seven days she is released in the hive. Usually this stops any further swarming during the season by colonies thus treated."—A. B. J.

THE VERY SAME. *First Small Boy.*—We had a little baby come from heaven to our house last night.

Second Small Boy.—Huh! that's nothin'; we had one went to heaven from our house last night.

First Small Boy.—Say, Pete, I'll bet it's the same kid.

AN AMERICAN MIXTURE that's sure cure for foul brood is mentioned in *B. B. J.*, and that skeptical journal expresses doubts about it, and says something about "wooden nutmegs." Now look here, Mr. J. Bull; we own up to the wooden nutmegs, but we don't want the humbugs of all creation saddled on us; and when one is gotten up on British soil, please don't put our label on it.

WHAT A BIT of spite can be shown by emphasis on some little word! When Mary marries John, Sarah (who has failed to catch him) says, "I *hope* Mary will be happy with him," and the special emphasis on that word "hope" predicts dire calamity for Mary. And now "ye editor" says, p. 104, "I *hope* the doctor's past record will enable him to live down such a report." Why couldn't he hush it up, as I do his failings?

THAT'S A NICE SCHEME of A. I. Root, to have a gain of a year by cutting crimson clover in time to plant corn on the ground; but, pray, where are the poor bees to have a chance then? Per contra, C. E. Thorne reports from Ohio Experiment Station in *Stockman*: "We have not yet succeeded in getting a satisfactory stand of this clover at the Experiment Station, though several attempts have been made, nor have we heard of its being successfully grown in this latitude.

GENERAL CORRESPONDENCE

HIVES, LARGE VS. SMALL.

SMALL HIVES MORE PROFITABLE. AND WHY;
A CAREFUL REVIEW OF THE WHOLE
MATTER.

By H. R. Boardman.

I have been discussing the matter in my own mind for some time as to whether any thing more could be profitably said upon this already thoroughly canvassed subject. I am quite sure, when the arguments are all in, could the vote be taken, no change would be noted in the use of hives.

It could not be possible that all of the bee-keepers in this great diversified land, from the cold North to the sunny South, could agree upon the same kind of hive, either in size or style.

Methods must be as various as the climate. This question of hives, then, is largely a matter of locality. I can speak for my own locality only, as to what hives or methods suit me best. I would not presume to discuss with the bee-keeper of the South or West as to what is best for his locality.

Much depends, too, upon what is sought to be accomplished—whether the apiarist is working for comb or extracted honey, or both together; whether he wants increase, or wants to prevent increase; whether he wants to se-

H. R. BOARDMAN.

cure all possible of the honey gathered, and supply its place by feeding, or depend entirely upon natural sources. It seems to me that, for the production of extracted honey, the tiering-up feature would be indispensable, whether the hive used were large or small; and it also appears to me, that a small hive is better adapted to this purpose than a large one. But I am a specialist in comb honey, and perhaps had better consider the question from that standpoint alone. In order that my prejudices as well as my preferences be more clearly understood I will describe my hive:

It is an eight-frame hive, taking a frame $12\frac{3}{4}$ x $12\frac{3}{4}$ in., inside measure. You will see that this enables me to use a wide frame for sections that holds 9 sections, 6 frames to the hive, or 54 sections in a hive. I have recently, within two

or three years, commenced using 9 frames in my eight-frame hive, in a space of 12 in., and the number so used is increasing each year. It gives some advantages that I will not describe here, only to say it gives very nice combs; so you may put me on record as favoring the eight-frame hive with 9 frames in it, and with the tiering-up feature. Let me say, first and last and all of the time, that, in an experience of 25 years, I have found my hive large enough for every time and place.

There are two principal points which I take into consideration in deciding the proper size for a hive: I want it large enough to hold sufficient winter stores, and also to furnish about the right capacity for brood for the average queen—average, I say, for I have never been able to have all of my colonies breed up uniformly. Some queens will outdo and go ahead of the rest, while others will fall behind. It is a prominent feature of my work in the beeyard during the early part of the season, when the bees are building up rapidly, to equalize the strong and weak colonies: and until I have all of uniform strength in the yard, and all built up to the full capacity of the hive, I think I have no need of more room: and with all in this condition I feel that I am well prepared for the beginning of the honey-harvest. I do, however, build up extra strong colonies sometimes by tiering up, which I will describe hereafter.

For winter stores I would consider it poor economy to have a hive larger than required, when well filled, to carry the bees through, and have the honey all cleaned out at the beginning of the honey-harvest. I should rather feed a little to bridge over than to furnish hive room, and tug in and out of winter quarters a lot of old stores that are worse than useless in the hive.

In the early days of my bee-keeping experience I used to buy bees in old box hives, and transfer them to movable-frame hives. These hives were of all shapes and sizes, and my work upon them gave me an excellent opportunity of observation, and I availed myself of this opportunity. Proper size of hives was one of the things I had in mind, and I satisfied myself that a brood-chamber of about 2000 cubic inches was near right; and the experience of many years since has confirmed that decision. In many of the largest of the box hives that I transferred, I found old stores that had been carried over from year to year until it was thick and waxy. I could not see how the colony could be benefited by this surplus of stores; and unless a knowledge of the reserve gave them a sense of security, I decided that such hives were too large. When hives were so small that brood-rearing had to be economized, I decided that these were too small.

LARGE SWARMS FROM BIG HIVES.

There has been a great deal said from time to

time about large hives giving large swarms—big booming swarms—and much heavy argument is brought forward to show the profit of these large swarms, and consequently the advantage of large hives. Now, isn't it a fact that the size of the swarm depends almost entirely upon the queen. Would any queen produce any larger swarm in a large hive than a small one, so long as she was not restricted in laying and the bees were furnished room? I think it is the laying capacity of the queen that regulates the size of swarms almost entirely.

Now about the economy of large swarms. How large would it be economy to have swarms? Of course, there is a limit beyond which it would not pay to go. A large swarm costs just as much per pound to raise as a small one; and who can tell what is a big booming swarm—how many pounds of bees? So far as I can remember, no one has thought to tell us just how many pounds of bees there are in a big booming swarm that issues from a big hive.

If we had a big pile of bees, as we sometimes do in the swarming season, when several swarms go together, how many would it be profitable to put together in a hive in dividing them up? I have sometimes hived these big abnormal colonies all in one hive, and given them room, and watched them with expectation of wonderful results. To be sure, they work very rapidly at first, and do more than an ordinary colony; but they never come up to my expectation. They soon become normal in size, and never make a record that will compare with the same amount of bees in two colonies.

During the swarming season last year my bees were in what I called very fair strength. In order to know just what my swarms were, I set them on the scales and weighed them before shaking them out of the basket. I found them to weigh 7 to $7\frac{1}{2}$ lbs., from single eight-frame hives. I could never see much gained by having swarms much larger than this.

BUILDING UP COLONIES BY TIERING UP.

I find no difficulty in getting brood reared in two hives by tiering up. In fact, I had thought that more brood could be secured by this method than any other I had ever tried. It involves some extra labor, and requires plenty of stores, unless honey is coming in. When a colony becomes strong, and needs more room, if a hive of empty combs be placed on top or over it, the bees will soon occupy it, and the queen will not be long in following. The empty combs, with a strong force of workers, make the conditions favorable for the queen to do her best, and she will not be long in filling the combs with brood. I do not expect the queen to continue laying in both hives at the same time. I do expect, and am not often disappointed, when the queen goes above, that she will continue work in the upper hive until it is full of brood; and unless honey is coming in, the bees will remove a considerable portion of the honey above also, thus leav-

ing the lower set of combs empty, or nearly so, as fast as the brood hatches. My hive being deep, no doubt gives different results from a shallow one. Bees are inclined to occupy the upper hive when tiered up. This I call forcing the queen. I can, if I wish to continue brood-rearing longer in both hives, set the bottom hive on top, and it is in the most favorable condition to tempt the queen above again. But it is not economy to push brood-rearing far into the honey season.

The tiering feature I find valuable in uniting colonies. I just place one colony over the other, with a honey-cloth or oil-cloth between, with a corner turned so that a small passageway enables them to get acquainted, and, after a few days, remove the cloth, place the hive to be occupied on top, with the queen.

In the same way I unite colonies when they are set out of winter quarters; but no cloth is necessary between the hives, nor is it necessary to kill one of the queens. Being of the same scent, they unite without confusion; and often both queens continue work for some time. There has been much of the best thought of our best apiarists expended in devising methods by which brood-rearing could be judiciously encouraged early in the season, when the colonies are light, and are struggling against vicissitudes of weather, with a large amount of brood to care for. Contract the brood-nest by use of division-boards and dummies, the use of cushions, and packing and care resorted to for the purpose of protecting the colony and economizing the heat. But these are all expensive, and involve much labor and continual fussing, and I think they are only arguments in favor of smaller as well as more properly constructed hives.

I have not called attention to the advantage of a small hive over a large one, in the lifting, carrying in and out of winter quarters, etc. The ground has all been gone over, but this I consider an important item not to be overlooked.

After all, the question is not whether A can get better results with a large hive than with a small one, but whether A can get better results with a large hive than B can with a small one under the same conditions.

East Townsend, Ohio.

[For a long time I have been more and more convinced, from various talks that I have had with Mr. Boardman, that he is one of the keenest, brightest, and most intelligent bee-keepers we have; and if there is a closer observer of Nature and her laws I do not know him. I have been trying to get him to write; but it was not until now that I have prevailed upon him to give us a series of articles, and the one above is the first installment. The subject he has taken up and handled so well is one that I assigned to him, as I believed him to be as competent as any one to review the whole situation, now that it is about time to draw the hive discussion, both large and small, to an end for the present. Mr. Boardman's articles will probably be somewhat of the nature of a review

of the literature that has appeared in the past in GLEANINGS.

I had expected in the present article that he would be somewhat on the "other side of the fence" in this hive discussion; but although he uses a different size of frame, it is somewhat encouraging to see that, with Doolittle and a host of others, and over a different route, he has settled upon 2000 cubic inches as the correct size of brood-nest. Mr. Boardman says he finds no difficulty in getting brood reared in two hives by tiering up. This is the position that some of us, in opposition to that practical bee-keeper, C. A. Hatch, have held, and I am glad to see one more good authority to sustain us in this.—Ed.]

A very interesting and valuable article quite in line with Boardman's views will be found in this issue, by G. M. Doolittle, on page 137.

BEE-KEEPING AS A SPECIALTY, NOT A SUCCESS.

FRUIT-GROWING AND BEE-KEEPING A GOOD COMBINATION IN CALIFORNIA.

By Wm. G. Hewes.

Essays advising that bee-keeping as a business be made a specialty by the persons engaged therein have been written from time to time. The essayists are often eloquent in their advice, but never, I believe, practice what they preach. One of the best of these articles was written by a gentleman in Michigan whom Ernest Root, in his recent bicycle-tour, discovered to have a very fine orchard. The "G. in M." has, no doubt, perceived, as has the writer, that the growing of fruit fits in more happily with the production of honey than does any other occupation.

The bees in this part of California require constant attention during the months of April, May, and June. During the remainder of the year, a few days' attention each month is all that is needed. Now, during the months of April, May, and June, when the bees need constant attention, the requirements of an orchard are only cultivation, and this simple work can safely be entrusted to any ordinary farm help. The specialist bee-keeper, by the first of July, is beginning to wonder how he is going to "kill time" for the next nine months (and if it be a dry season following, he will have to kill time for the next twenty-one months); but the fruit-growing bee-keeper quits his extracting to attend to the drying of his apricots; and from apricots he goes to peaches, to prunes, to pears, to grapes, to figs, to apples, almonds, olives, or oranges, as the soil or climatic conditions of his locality make most profitable. By a proper selection of varieties the fruit-growing bee-keeper can harvest fruit from the end of his honey harvest until the beginning of the winter rains, at which time he has leisure to plow his orchards and paint his hives, thus occupying the whole year in a way conducive both to his happiness and his profit.

Numerous have been the devices of bee-keep-

ers to "kill time" during the eighteen months which have elapsed since we last had honey to extract. Some have got a "job" on fruit-ranches, others roam the hills with guns, potting quail and rabbits for market; and others again have retired to the mountain fastnesses with pick and shovel, to delve in the gravel of the creek-beds for gold dust; but their realizations are generally smaller than their anticipations. Only once have I heard where, in this seeking after gold, the realizations equaled the anticipation. But this bee-keeper did not dig his gold, for he was a bold bad bandit and wrecked a train. The sacks which he carried away are said to have contained \$20,000. In course of time he was captured, and now he will never "herd" bees again, for both himself and his partner (a nice young man from the Salvation Army) are living in strict retirement.

I wish here to place myself on record as saying that the making of bee-keeping in California a specialty is the acme of asininity. Many bee-keepers owning plenty of land do not even grow fruit enough for home consumption, believing it can not be grown excepting on those lands which can be irrigated. If they will plow deep, and then with harrows and clod-crusher pulverize the soil to the fineness of meal, and by constant cultivation keep it so, they can grow any thing. I care not how deep down it is to water. I have planted grape-cuttings, and gathered a bunch of grapes from them the same season. From apricots and peaches I have gathered fruit eighteen months after planting the tree; and almonds, pears, and prunes will give fruit in from three to four years after planting.

Newhall, Cal., Jan. 20.

[If I understand you correctly you are not a firm believer in bee-keeping as a specialty; and you point to the gentleman in Michigan, who has been an advocate of this doctrine, and say in effect he is not a practitioner of what he preaches. Mr. Taylor—and I presume this is the chap to whom you refer—makes a success in both lines, and very possibly he would of bee-keeping alone in good seasons; and, moreover, I understand he is a good lawyer; and that being the case he may and probably does get some revenue out of that profession. But during the past few poor honey years in Michigan, when many of its bee-keepers were glad to average even 10 lbs. per colony, Mr. Taylor would not have found bee-keeping a good bread-and-butter specialty. One of the hardest blows to the idea of bees as the sole bread-winner has been the series of poor years. During the good old-fashioned years, and Mr. T. probably had reference to these, such as we *used* to have, when bees every year brought to their owner some returns, the specialty business was a success. But now I believe I can almost count on the fingers of my hands the number of men who derive their living largely from bees; and if I except from that number those who have absolutely no other source of revenue there is scarcely one. But take it in other branches of agriculture, those who make a specialty of any one line are very few. Even our friend T. B. Terry, who has been a strong advocate of specialty on the farm, and one who used to grow

potatoes exclusively, and buy his other products, I believe now makes quite a business of growing strawberries, and lecturing throughout the State.

Well, then, if we accept the idea that specialty in bee-keeping to-day is not common, what other lines of business combine with it nicely? The one already mentioned—fruit-growing—is one of the best. Poultry-raising is also connected with it; but as a general thing you will find that the great majority of our bee-keepers are practical farmers, and that their bees are only a side-issue.—Ed.]

OUR HONEY RESOURCES.

HOW TO INCREASE THEM; A VALUABLE ARTICLE REVIEWING THE ATTEMPTS THAT HAVE BEEN MADE IN THE PAST.

By C. H. Dibbern.

Ever since I commenced bee-keeping, some thirty years ago, it has been a constant study with me how to increase the yield of surplus honey. Many a time during my enthusiastic periods, when the flowers yielded abundantly, I have thought that, owing to some device I happened to be trying at the time, I had "struck it rich," and visions of future wealth and position in the bee-world would loom up in the dim distance, only to be dashed to earth when the poor years came again. Indeed, bee-keepers seem to be of such a hopeful disposition, that, during years of abundance, they quickly jump to the conclusion that the coming years will all "flow with milk and honey," and that the hard times, when the flowers are scarce, or will not "give down," are indeed past for ever. However much we may have indulged in such thoughts, the recent few years of poor yields, and failure, have dispelled the illusion.

My first efforts to overcome short yields was to "invent" a new hive that would enable the bees, by its peculiar shape and heat-economizing principles, to secure the honey whether the flowers yielded or not. This worked all right while the years remained propitious; but when poor honey seasons came again, I came to the reluctant conclusion that, after all, not so much depended on the hive as on some other things.

About this time comb foundation made its appearance, and I straightway made up my mind that this was the long-sought desideratum. Why! was it not perfectly plain that all we need to do was to give the bees frames and sections, filled with these waxen sheets, and, presto! combs of nice sealed honey. But this, too, the hope-destroying poor years soon laid low. It was soon understood that, though it was an excellent thing to secure nice straight comb when honey could be found, it was utterly useless when the flowers refused to yield.

About next it was the particular strain of bees that was to give us the great yields. The superior honey-gathering merits of Italians, Carniolans, Cyprian, *et al.*, were duly extolled. Some of our enterprising queen-breeders even

tried to improve on these well-known old-fashioned names by advertising "Golden Carniolans," "Punics," "Five-banded Italians," and "Red-clover" queens that "just rolled in the honey." Well, the "rolling" business struck most of us, who had met so many disappointments, very favorably, and many of us sent off our money-orders and received the coveted queens in due time. But again the poor seasons soon taught us that even the most industrious bees could not "make" honey.

Then it was thought that, by manipulation, the desired results might be secured. Then the non-swarmer craze, the doubling-up plan, and non-swarmer devices; making two swarms work in the same set of supers had its day; but, strange to say, not much is heard of them of late.

Now, I believe most bee-keepers who have been engaged in the pursuit for 15 or 20 years have had just about the experience here related, and I do not wish to be understood as running down these efforts to improve our calling. I fully believe that all these things have been of great advantage. The hive, foundation, the kinds of bees, the manipulation, are subjects that can not be overlooked by the person who may hope to be successful.

I think that most of us have learned that, really, there is no short cut to success in bee-keeping. The desire, however, to advance, and take advantage of every suggestion and improvement, if it really is an improvement, is a laudable one, and should be encouraged. It has long appeared to me that the most promising field to increase our surplus-honey yield was to increase our honey-yielding flora. It is, perhaps, well enough to hunt to "the ends of the earth" for better bees; but why not send practical bee-men to study the honey-plants of other countries, with a view to introducing them here? It must be that some of the plants that yield so abundantly in other countries would do equally well here. Our linden is rapidly disappearing; and the white clover, owing to our scorching summers and snowless winters, is almost a thing of the past. It is becoming quite evident that something must take their places, if we may expect honey-yields in the future.

Some fifteen years ago I commenced sowing honey-plants in waste places, about stone-quarries, along creeks and rivers, wherever a suitable place offered, and where no objection would be likely to be raised. I have tried about all the honey-plants that have attracted attention, including Simpson, Dr. Tinker's golden, Chapman's, Rocky Mountain, etc., and I now find some of these plants growing in the most unexpected places. The plant, however, that has given decidedly the best results, and one that is able to hold its own against all the world, is sweet clover. It is a "dandy," as Mr. Muth says, and, no matter what the season or

the weather, it can be depended on to furnish a fine quality of honey.

Some years ago I rented from three to five acres of land adjoining my apiary, and kept it in sweet clover for a number of years. While so small a field did not give a yield of surplus honey to 150 to 250 colonies of bees during poor seasons, yet it kept up brood-rearing, and often gave me some surplus from fall flowers that I should not have secured otherwise. Strange as it may seem, the sweet clover has now spread for several miles, growing wherever it can gain a foothold; and in a few years more it will, no doubt, be the main honey-plant in my locality. I am glad to see such men as M. M. Baldrige write about sowing 80 acres to this plant, and shall anxiously watch the result. I see no reason why Mr. B. could not make it a paying crop for seed alone; and 80 acres of sweet-clover bloom, in the immediate vicinity of an extensive apiary, is a factor not to be despised. I have often wondered why farmers did not make more use of sweet clover as a forage plant and for fertilizing. I know of several hog-lots, of from 10 to 20 acres, that have produced nothing but dog-fennel for the past ten or fifteen years. Why not plow up, say, half, plant to sweet clover, and keep the hogs off for the first year? The next spring, plow and seed the other half and turn the hogs in to live on the tender clover-shoots. If not overstocked, enough clover would bloom and seed the ground to keep it from running out. Incidentally the neighboring bee-keepers would be benefited. Who will try my plan?

Of course, it is always a good plan to do what we can to induce farmers to sow alsike clover, buckwheat, and other honey-producing plants. One trouble with this idea is, that usually, when clover, alfalfa, etc., begins to bloom, the farmer appears with his mower and cuts it down. But it often happens that, if you can convince the farmer that the seed of the alsike, alfalfa, etc., will pay well, he may be induced to let it stand till done blooming, and thus give the bee-keeper the full benefit of the bloom.

Milan, Ill.

[As Mr. D. says, there is no short cut to success in bee-keeping. But there are a great many conveniences or "little comforts," as some have called them. A good point is made in utilizing the waste weed-patches. Sweet clover is a sort of weed; but if nothing but weeds will grow in these places, put one there that will be worth something. Dr. Miller is a firm believer in this doctrine; yes, he practices what he preaches; but don't tell him that I said so.—ED.]

HONEY-PACKAGES FOR EXTRACTED HONEY.

WHY HONEY-BARRELS LEAK SOMETIMES; THE REMEDY; ANOTHER VALUABLE ARTICLE.

By E. France.

In GLEANINGS for 1894, page 633, the editor makes a plea for tin cans. I think cans are all

right for small lots. I would a great deal rather handle a large crop in barrels. I have tried tin cans, and do use some yet for small shipments. For large lots barrels are cheaper, ship for less freight, in less carload lots. I don't know how it would be in car lots. When extracting in our out-apiaries we can with less trouble put the honey in barrels, and load them easier, than we could cans. With a pair of skids three or four boys will roll into a wagon a few barrels very quickly, whereas cans would have to be lifted in two at a time—heavy work; and when the cans are used, and the honey gets candied, they are a miserable thing to get the honey out of. First the cans must be filled full to hold 60 lbs. Now, it must be melted to get the honey out; and unless you are especially fixed for the work it is no fool of a job. I have set a can in a wash-boiler; have set them in the water-reservoir back of the stove, and it takes a long time to melt, as the honey is in one solid chunk. The screw-cap must be taken off; then, ten chances to one, the honey will swell up and run out of the top before it is melted, making a loss and a muss; and a 60-lb. can is a pretty heavy thing to lift up high enough to put into a boiler on the stove. First-class oak, iron-bound barrels cost me, made here, \$1.50 each, holding 370 lbs., warranted not to leak. I have handled our honey in such barrels for several years, and they do not leak.

As for melting the honey in the barrels, I don't do it. I take the hoops all off at one end of the barrel, then the head will come out. Take out the head, drive on the hoops again. Now dig the honey out of the barrels, and melt it in a tin pail; set in a kettle of water over the fire, or melt it in whatever you please; but have your melting-dish set in water to prevent scorching the honey. I can pack honey in barrels, and sell it for half a cent a pound less than if packed in 60-lb. tin cans; and then the shipping freight is a good deal less.

But there is a growing demand for 60-lb. cans. I suppose that is for the reason that such kegs as molasses is packed in are not suitable for honey-packages. They are too frail, and leak. A good oak keg, made suitable to hold honey, costs too much. When I first began to extract honey I had very much trouble to get a good package. I went to the best cooper in town, and bought some kegs that held 140 lbs. of honey—oak, with iron hoops. Being a cooper myself, I thought they were all right. He brought them out of the cellar. I took them home and filled them—14 of them; also got one barrel that held 500 lbs. I had them in a room above ground. In a few days they began to leak, and made me a great deal of trouble. That year my home market took all the crop at retail, so I had all the kegs left over to fill again the next year. I made up my mind that honey kegs and barrels should be kept in a dry place; then, as fast as I get one empty, I

put it upstairs in the shop, first washing the keg out clean inside, and putting in the head. I let them stay there and dry out until I wanted them the next year. I got some new barrels made and put them up stairs also. Result—when I wanted them the next year they were dried out. I drove the hoops, and they were tight. I filled them with honey, and there was no leaking. We have never been troubled with leaky barrels since. We now have our barrels made in the winter. We put them in a dry warm place until wanted; and if they are well made they won't leak. It won't do to keep honey-barrels down cellar. Barrels will soon leak when taken from the cellar and filled with honey. Honey doesn't seem to keep barrels from drying out. Leaky barrels filled with water will soon swell and hold water; but not so with honey. It won't do to pick up any thing you may find down town, for honey-packages. They will be sure to leak, as they are kept in a cellar. I think the honey will pay for a good package, clean and tight.

After we had found out how to fix barrels so they would not leak, we found we could save a little money by buying barrels that would hold 530 lbs. in place of the ones we were using, that held 370. The small ones cost \$1.50, the large ones \$1.60, so we got 50 of the large ones. We found the large ones unhandy. They are too big. A 370-lb. barrel is about right, we think. For retail trade we use tin pails. One and two quart sizes take the best in Platteville. Platteville, Wis.

[Many of the difficulties between the bee-keeper and the buyer of honey is over leaky barrels. The one says that so much honey was lost, and the other doubts his statement, and so on the trouble goes. All of this may be avoided by reading carefully what Mr. France has to say above. The trouble in many of the cases is not so much with the commission merchant or buyer as with the producer, or, rather, his (the producer's) lack of knowledge. Although the Dadants the Muths and ourselves have repeatedly said that barrels should be kept in dry places, and that they should not be soaked with water before putting in honey to make them tight, yet almost every year there are a lot of bee-keepers who go on and do this same thing, and as a result reap the natural consequence—loss of honey, and a distrust of the buyer. I think it would pay every bee-keeper who ships his honey in barrels or kegs to paste this up in his honey-house, where he can read it once in a while.

The editorial referred to was by our business manager, who has had some of the troubles above mentioned, and his solution of the difficulty seemed to be in the use of tin cans. When I visited Mr. France last summer I saw stacks of barrels of honey that were perfectly tight, not even showing the least trace of leakage. These same barrels, as Mr. France explains, were bought some time ahead, and kept in a dry place, and allowed to shrink all they would; then after being carefully coopered up they were ready for the honey.

Regarding the square cans and barrels, it seems to be largely a question of locality. In California and certain parts of the West, on account of the dry climate, square cans are used as

a matter of necessity. In the New York markets, and in Albany, I found that barrels and kegs were preferred by all the commission men and buyers. Two square cans in a box, they claimed, were heavy and unwieldy; and then if they were dropped, a bad leak was the result. One commission man, I remember, told me he would not have a square can of honey in his place if he could help it; that there was no reason for kegs and barrels leaking if the producer only understood his business, and that, in his opinion, it would not take them very long to learn after they had shipped honey once or twice, and had about half of it lost by leakage.

I suppose much of the trouble from leaky barrels is owing to the fact that second-hand molasses-barrels, none too good in the first place, were used. The Frances, you see, buy new barrels and make sure that they get good ones at that.

This article will be seasonable, inasmuch as it is the proper time now to procure your barrels for next year. They should be put up in a dry room, where they can season thoroughly.—Ed.]

CALIFORNIA ECHOES.

By Rambler.

Great Scott! I have just learned that there are 191,988 bachelors in California.

It is a real pleasure to receive the first numbers of the bee-journals for the new year. All show a progressive spirit, which is a sure indication that the industry is marching on. Glory hallelujah!

Hum! pull the cobwebs outen your ears, and listen. The word bee-paradise is floating in the air. Mr. Blankton, of Beeville, Tex., in *A. B. J.*, says, "This is, no doubt, the bee-paradise of this continent."

Some time ago Dr. Miller wondered or speculated why the queen-bee has a curved sting. Did you ever see a queen-bee sting a rival in her cell? She clings around the cell; and the sting, following the curve of the body, strikes the rival in the thorax. Of course, the sting has to be curved to "get there."

That was real mean for Mr. Thilman to say that our beautiful white-sage honey tasted of alkali. Why, bless you, sir, our sages do not grow in the alkali lands. We have but little alkali lands here anyway; and where there is much alkali the ground is barren. No, sir; you will have to taste again; then taste of that basswood honey, and see how minty it tastes.

In *A. B. J.*, Bee-master says: "A narrow belt of the Dominion of Canada, extending from the Atlantic to the Pacific, has no superior as a honey field anywhere in the wide, wide world." Gallup says, "So California is not only the bee-keeper's but the old man's paradise"—enough paradise for two. Paradise is also found in Florida, Cuba, heavenly Topolobampo, and Australia. So paradise seems to depend upon how much the love of one's locality is diffused over the cerebrum. It is clearly a brain trouble. Dr. Peiro, what shall we do with these fellows?

I note that Dr. Miller is troubled about stopping cracks in boxes. Beeswax, if run into corners of boxes, is sure to scale and crack. Try paraffine. It is free from the habit of cracking, and sticks well. Quite a loose-jointed box can be made water-tight by fitting into it a piece of canton flannel; but before fastening it in, saturate it thoroughly with hot paraffine, then secure with small tacks, and your box is water-tight. That is the way I make cheap trays for photographic work.

There, now, those Canadians are trying to get ahead of me on that magic-lantern business. I had that very idea maturing and experimenting on slides, when they popped up with their lantern plans. Well, this is a big country, and I think there is room for several operators of the slide; and there is a splendid opportunity in this direction for the proper education of the public in relation to bee-keeping, methods of work in the apiary, the opening flowers, and a hundred interesting things. I wonder if we can not get up a bee photographic magic-lantern exchange club. What do you say, friends, in Canada?

I notice, Mr. Editor, that your proof-reader, or some one else, in seeking to correct my pronunciation of Spanish names, is making some mistakes that will, of course, fall upon my head. The Spanish as spoken here is not the pure Castilian. It is corrupted more or less; and when I give the pronunciation after a word I give it just as I have heard it spoken scores of times. For instance, in *Ramble* 123 I used the name *Jolon*, a town. It is pronounced *Holoné*, and your interpreter put it *Jo—*, which is wrong, as he of course knows, for all Spanish words having a *J* in them are pronounced as an *H*; as, San José (Hosay), or San Joaquin (Hoaquien), or, as it is popularly pronounced, here, Wauk-éen. Then in the same *Ramble* Gonsales is fixed over into *goan-saw-lais*. Now, that is near the *Castilian* pronunciation, but here it is cut short, and is pronounced as *gun*, or *gn-saw-lis*. I mention these words, and especially "*Jolon*," for California readers will notice the wrong rendering, and accuse me of being a tenderfoot.

[Regarding the Spanish words, it was a typographical error that we did not represent *Jolon* as if pronounced *Ho-lone*, as a Spanish *J* is a Yankee *H*; but Rambler makes three syllables of it, as if pronounced *Ho-lo-nay*. In this regard we fear he stands "*H'loné*." We believe that even those who speak Spanish with a brogue would regard the figured pronunciation of the other words as correct, from the standard of the Spanish Academy. The trouble was, if any, the pronunciation was *too* exact. We have always tried, and shall continue to do so, to give Rambler's exact meaning; and in the case in question we are glad we got it *too* good rather than *too* bad. So far we have followed Rambler very closely in his travels, by means of a map, lexicon, and Spanish books, and have tried to verify every word printed.—PROOF-READER.]

WEED SEEDS SOMETIMES FOUND IN CLOVER SEED.

AN IMPORTANT WORK BY THE NORTH CAROLINA EXPERIMENT STATION.

Bee-keepers have more or less to do with all the clovers; and as there has been in times past quite a little trouble in regard to various seeds, and some discussion as to what these seeds were, we have thought best to extract the following from Bulletin No. 108. of the North Carolina Experiment Station, which station has kindly loaned us the cuts given:

THE CLOVER FAMILY.

The clovers are the most frequently adulterated, and generally the foulest samples found in the markets. Crushed quartz rock, either plain or colored, to resemble true seed, has been frequently employed where dealers do not fear detection. Old, discolored, and worthless seeds are often dyed, and mixed

FIG. 18.—PLANTAIN.—a, fruit, with attached corolla; b, the 4 corolla-petals; c, twin seeds; d, the inner surface of seeds; e, back of seed; f, seed, natural size.

with fresh seed. These "doctored" seeds can be detected by pouring some of the seed upon a clean white cloth, slightly moistened, and rubbing the seeds thereon. The cloth will remove the artificial coloring, and show it. Quartz grains can be readily detected by examining the seeds with a magnifying-glass. "Uncleaned" samples often contain a fifth of their weight in weed-seeds, the most common of which are plantain (*Plantago lanceolata*, Fig. 18),

FIG. 19.—SHEEP SORREL.—a, seed in hull; b, a naked seed, enlarged size; c, natural size.

FIG. 20.—CHICKWEED.—a, natural size; b, magnified; c, same in profile.

sheep sorrel (*Rumex acetosella*, Fig. 19), chickweed (*Cerastium triviale*, Fig. 20), pigeon-grass (*Setaria glauca* and *S. viridis*, Figs. 21 and 22), ox-eye daisy, dog-fennel, and buttercup. Seeds of a parasitic plant commonly known as dodder, "devil's-gut,"

FIG. 21.—PIGEON-GRASS (GREEN).—a, back and front views, enlarged; c, even a trace of seeds, natural size.

of this foul parasite should be rejected, whatever be their price. A full account of this weed was given in Bulletin 70 of the North Carolina Experiment Station. Alsike-clover seed (Fig. 25) is largely imported from Europe, and is apt to contain dodder-

FIG. 22.—PIGEON-GRASS (YELLOW).—a, magnified to show marking; b, natural size.

seed (Fig. 24—on the ground), which, being of nearly the same size as the clover-seed, is very difficult to get rid of. Uncleaned samples are more or less infested with seeds of buttercup, plantain (Fig. 18), sheep sorrel (Fig. 19), and chickweed (Fig. 20).

FIG. 23.—FLAX DODDER.—a, natural size; b, magnified; c, double seeds.

FIG. 24.—CLOVER DODDER.—r, section of a seed; c, endosperm; v, vegetation point.

FIG. 25.—ALSIKE CLOVER.—a, natural size; b, side view showing rootlet; c, profile view.

Crimson-clover seed is generally much cleaner than other clovers, and the samples are not often adulterated. The most common impurities are plantain (Fig. 18), ox-eye daisy, and sheep sorrel (Fig. 19).

Japan clover is usually sold in the husk, and is not adulterated; neither does it contain as impurities other kinds of seed, for *Japan clover* permits no other plant to grow among it.

FIG. 26.—COMMON PIMPERNEL.—b, double fruit; c, d, single fruit, back and front view, enlarged.

Samples are, however, often very dirty with sticks, stones, and trash. In dry seasons the seeds do not fill well. Good seed should weigh 24 pounds to the bushel.

FIG. 27.—RAGWEED.—b, hulled seed, with pappus; a, natural size.

Lucerne seed is largely imported from Europe, and is apt to contain dodder (Figs. 23 and 24), plantain (Fig. 18), common pimpernel (*Pimpinella saxifraga*,

FIG. 28.—RANSTED-WEED.—a, b, front and profile views; c, natural size.

Fig. 26), and seeds of composite weeds. American-grown seed-samples are apt to contain seeds of hog-weed (*Amarantus spinosus*), dog-fennel, and pigeon-

FIG. 29.—RAGWEED.—c, without pappus, and put open; d, natural size; e, naked seed; f, section of seed, showing cotyledons.

grass (Figs. 21 and 22). European lucerne-seed is generally better than American-grown seed. The best comes from Provence, in France.

FIG. 30.—CORN COCKLE.—a, natural size; b, magnified.

FIG. 31.—WHITE CLOVER.—a, natural size; b, side view, showing rootlet; c, profile.

Red-clover seed is not now imported from Europe. The most common adulterants are quartz grains, which can be detected by using a magnifying-glass. Uncleaned red-clover seed is probably the foulest seed on the market. The most common impurities found are plantain (Fig. 18), sheep sorrel (Fig. 19), pigeon-grass (Figs. 21, 22), ragweed (*Ambrosia artemisiifolia* (Figs. 27, 29), raised-weed (*Linaria vulgaris*, Fig. 28), corn cockle (*Agrostemma githago*, Fig. 30), dog-fennel, ox-eye daisy, and wild carrot. Dodder (Fig. 24) is also apt to be present in samples of red clover, though not so frequently as with lucerne. The least trace of dodder-seed should condemn the sample.

White-clover seed—shown in Fig. 31—is, to some extent, imported from Europe, and it is sometimes adulterated with old and dead seed, colored and doctored with sulphur, to resemble fresh seed. Quartz seed; b, d, different views, magnified.

White-clover seed—shown in Fig. 31—is, to some extent, imported from Europe, and it is sometimes adulterated with old and dead seed, colored and doctored with sulphur, to resemble fresh seed. Quartz seed; b, d, the naked seed; a and b, grains, either plain or colored, are used for the same purpose. The most common impurities in badly cleaned samples are plantain (Fig. 18), sheep sorrel (Fig. 19), and spurry (*Spergula arvensis*, Fig. 32). Dodder may be present in samples of white clover, but it does not affect this species as much as it does red clover, alsike clover, and lucerne.

FIG. 32.—SPURRY.—a, natural size; b, c, d, different views, magnified.

FIG. 33.—SAINFOIN.—a, c, the hulled seed; b, d, the naked seed; a and b, natural size.

THE SEALED-COVER QUESTION REVIEWED.

WHY THEY WERE CONDEMNED.

By A. S. Martin.

Friend Root:—I would ask those who make such a handle of bees wintering in cracked hives and rent hollows of trees if they ever took the trouble to observe the situation of the cluster. Were the bees really exposed to the draft from those crevices? Pshaw! nonsense! they can not be induced to form their cluster in the midst of an upward draft, if they can possibly avoid it. In all these cases it seems certain they were able somehow to shun it. Those reports in GLEANINGS, seemingly so adverse to sealed covers, appear to me exceedingly defective and unsatisfactory. They almost, without exception, ignore bottom ventilation. How can such reports give the "black eye" to sealed covers, or "seal their fate"? The trouble seems to have been with the sealed or partially sealed bottoms. The interior of a hive with close walls and sealed cover is practically a dead-air

space, subject to no fluctuations but such as the bees themselves create, provided the hive is as it should be, sheltered from the wind. In such a hive, bees have perfect control of ventilation, as* Nature evidently designed they should have. They will ventilate perfectly such a space if they have free access to the external air. They do it in summer, and why not in winter? They are not then helpless hybernants, as some seem to suppose. They arouse at intervals and attend to their needs, and are never all asleep at the same time. You can hear them at all times.

Mr. Quinby's reversed hives had no upward ventilation. Mr. Taylor's results with lots 1 and 2 (see June 1st GLEANINGS, of 1893) prove nothing more than that such methods may be practiced with impunity in a temperature of 42°. In summer he can go still further—leave both tops and bottoms off, and his bees will not perish if he will only give them shade and shelter. But what shall I say of lot No. 3? The damp interior, the wet moldy combs, the dead bees, conjure up visions of the Black Hole, of Calcutta. Mr. Boardman and others use sealed covers and have no such results. Why? Because they provide *sufficient* bottom ventilation. Bees must have fresh air, and plenty of it; but how can you by upward ventilation adjust the supply to their needs? You can't do it, and needn't try—too much or too little. In either case your bees are injured, if not destroyed. The mere fact of their living till spring is no proof that they have not been injured. Discomfort, sleeplessness, the wear and tear of their efforts to keep warm, fit them admirably for the process of spring dwindling.

Bees do well under sealed covers in Virginia. I have kept them thus 45 years, and have never lost a colony in winter but by starvation or thieving. Perhaps Nature did not design them to live in more northerly climes, hence their propolizing instinct is there at fault. In order to do well they should there be endowed with a penchant for such abodes as disused chimneys and stovepipes, and, like bumble-bees, roof their nests with old rags, moss, and bits of stubble.

Dear brothers, I am not trying to ridicule any of you; but I can't help pointing a jeering finger at the long ears of this ridiculous thing called upward ventilation. If you will stick to upward ventilation, suppose you try the cracked-hive plan. Seal a cover over $\frac{3}{8}$ or $\frac{3}{4}$ of the frames, or of their length, and then cover this and the remaining space with your absorbents, cushions, etc. May be this will prove a happy compromise. I use heavy cotton cloth, thoroughly saturated with melted bees-

*When a medical student I was taught to follow the indications of Nature. I have ever found this to be a safe rule. There are those who scorn it. But Nature appears to me a something sparkling all over, and radiant through and through with intelligence.

wax, sealing it to the tops of the frames and upper edge of the hive with a hot iron. On this waxed cloth I place six or eight folded newspapers, and over all an inch board with a brick on top to keep it in place; entrance, $\frac{3}{4}$ x 16 inches: hives on summer stands, sheltered from westerly winds.

Roanoke, Va., Nov. 27.

[Dr. Martin advocated the sealed cover back in '84. He was quite disappointed that they should have been so hastily condemned last spring.—Ed.]

RAMBLE 126.

AT PRYAL'S AND THE STATE UNIVERSITY.

By Rambler.

The towns became more numerous, railroads ditto; telegraph and telephone poles with their burden of wires ditto; also vehicles on the road, all the way from a road-cart up to the many-teamed wagon, the elegant carriage with happy-looking smiling ladies; the equestrienne with bifurcated skirts, and some, more sensible, with skirts, and the appendages they cover, carried on a side-saddle, according to the old plan. All of the above and much more made us feel a little out of place, in our rough traveling-garb, for we were being drawn irresistibly by the throng to those great business-centers, San Francisco and Oakland.

It is always best to prepare for an emergency before we emerge into the emergency. We therefore camped early at the pretty little town of San Lorenzo, 12 miles from Oakland. We here razored our faces, shampooed our shoes, and made such changes in our wearing apparel as we thought would enable us to pass for a couple of well-to-do members of the rural community.

Our black shirts (not black from dirt, by any means, but dyed black early in their manufacture, and quite fashionable with people who travel in the dust) we exchanged for the white variety, with collars to match; and various other garments, which had been packed away for so many weeks, were donned; and in the morning, when we again started on our journey, it seemed to me that we had left two other fellows behind at San Lorenzo. In our better habiliments we drove direct into the center of the fine city of Oakland. We found Telegraph Avenue, and, following it out several miles, finally landed at North Temescal (which is really only a suburb of Oakland), and at the home of Wm. A. Pryal. Of course, you all know Mr. Pryal as a genial writer for the bee-journals. He is a bee-keeper and queen-breeder; and before going further I wish to introduce his visage to you through a half-tone; and, better yet, I wish to say right off, and say it loud—yes, I want to shout it—he's a bachelor! ha, ha, ha! Let's shake, Mr. Pryal—ha, ha! shake again; shake, Wilder. Well, aren't we

three just as happy as three big sunflowers? After our sort of ebullition, and jubilee of fraternal feeling we camped upon a cozy corner of the Pryal property. Upon one side of us was the murmuring waters of the Temescal Creek, over us the tall gum-trees, whose leaves also murmured in the evening breeze that came fresh from kissing the waters of the grand Pacific Ocean. Fruits, flowers, and vines were growing in profusion all around the Pryal homestead, and in such variety as would bewilder the eyes of the novice, and doubly bewilder the nose with the various flower-scented perfumes.

W. A. PRYAL.

Mr. Pryal resides under the paternal roof, and the apiary nestles snugly under the fruit-trees near the house. The senior Pryal came from the Emerald Isle, and made himself a home in the Golden State in the early days of its notoriety. Mr. Pryal, senior, is a horticulturist of note, and one of the first to engage in that business on this coast. On this fruit-ranch are found many rare fruits, shrubs, etc. He was the first to import several varieties of plums from Japan; and the other rare specimens in the horticultural line, in which he has been and is interested are too numerous to mention. Owing to the dull times and the great railroad

strike, fruits of all kinds were wasting on the ground. Nearly all of a fine cherry crop was lost. Pears, peaches, apricots, plums, were rotting in profusion.

Mr. Wilder and myself made a pretty good market for quite an amount of fruit; but the market could not stand the shock of such a variety, and soon became overstocked.

Wm. A. has been interested in bees several years, but has never owned as large apiaries as we see in Southern California. His present apiary numbers about 50 colonies. The yields of honey here are not so astonishing as we find further south. The resources are from a different flora, or, rather, a more mixed flora, and the honey is several shades darker than our white-sage honey. I was pleased to note,

been a dull one he started off with many customers. His location is excellent for shipping queens to the various islands of the Pacific and to Australia.

Mr. P. has two efficient helpers in his younger brothers; but I fear the male trio of bee-keepers in this family will soon give up the bee-business. Wm. A. is just now interested in furthering the interests of the New Water Co., of Oakland; Charley and the other brother are mechanical geniuses, and are going to make things hum with electricity. I greatly fear that the care of the apiary will devolve upon the several young ladies in the house. I have no doubt but they can rise equal to the occasion when the occasion arrives. Among other distinctions, Wm. A. and the other brothers

APIARY OF W. A. PRYAL, NORTH TEMESCAL, CAL.

among other honey-producing trees, the linden, or basswood, growing thriftily on the avenue. This is a fine shade-tree here, and I have seen it in a limited way in other cities on this coast. Its growth demonstrates that it will thrive in any moist locality, either from ocean humidity in the shape of fogs and rain, or in the irrigated districts. Although its habit is not so beautiful as the evergreen pepper-tree, its honey is so far superior that it would be a blessing to bee-keepers to see it replace the pepper-tree.

Although the honey produced here does not rank as the whitest, its flavor is such that Mr. Pryal finds a ready sale and good prices for all he can produce. The dovetailed hive with all its appurtenances is used, and is considered the best all-round hive for this locality.

Mr. P. has recently directed his attention to queen-rearing; and though the past season has

and sisters are native sons and daughters of California.

The next day after our arrival, Aug. 4, we followed the footsteps of our host and tramped over the hills to the State University. Berkeley is chiefly noted for having this California institution located within its limits. Prof. C. W. Woodworth had attended our State convention; and the University, or the department under his care, was making an honest effort to aid bee-keepers, and disseminate knowledge in relation to the honey-bee. We three felt it our duty to call, and also help in our feeble way. Although the University was enjoying a vacation we found Prof. W. at his post. In his laboratory in the Agricultural Building we were shown bees preserved in alcohol, in all stages of development, from the eggs to the mature bee. In the attic were stored the vari-

ous implements for the successful management of bees. Prof. W. had tried to work a colony of bees in this attic; but as they had to fly up some twelve feet to the cupola above for an exit, and would just as often fly still further up and dash their brains out against the skylight, their usefulness was much curtailed, and the plan abandoned. Prof. W. will next make a platform in the cupola, and conduct the entrance through the slats. In this way the bees will have a fair field all to themselves, and escape the dangers of the skylight.

The department in which Prof. W. labors is ready and willing to aid bee-keepers in the way of experiments or the naming of various honey-plants now unknown to bee-keepers. The bee-keepers of the State are alone to blame if the University does not seem to make much advancement. With a proper backing by the fraternity, great results might be expected from the State University.

Prof. W. kindly escorted and introduced us to the various features of this great University. The great oaks, among which the buildings are located, and the multitude of other trees and shrubs from every clime the sun shines upon, make this feature alone one of deep interest. The honey-bee can here revel in blossoms, the native home of which is in the tropics, thousands of miles away; remote islands also contribute their floral treasures. We felt as though several days might be spent here profitably instead of a paltry hour or so. The professor returned to his duties; and as the shades of night were falling, we roamed over the hills again to the Pryal home.

EXPERIMENTS IN FEEDING BACK.

By R. L. Taylor.

Ed. Gleanings:—At your suggestion, that I give my views of your comments in Jan. 15th No., page 64, upon the results of my experiments in feeding back, I will attempt to point out some of the things which you appear to have strangely overlooked in your criticisms, and which, it seems to me, have led you to arrive at faulty conclusions.

As to the market price of the kinds of honey under consideration, you say: "According to the Honey Column in this issue, extracted honey of good quality brings at wholesale 7 cts., and comb 12." Now turn to the Honey Column of that issue and you will find that, in the markets most accessible to us, viz., St. Louis, Chicago, Cleveland, Detroit, and Cincinnati, the best comb honey ranges in price from 14 to 16 cts., and white extracted from $5\frac{1}{2}$ to 7 cts. Now, you must admit that it would be fair, for the purposes of the calculation, either to take the highest price of each kind or else the lowest price of each kind. It evidently would not be just to take the highest price of one and the

lowest price of the other to work out the comparison. But you by some oversight have done even worse than that, for you have taken 7 cts., the highest price of extracted in these quotations, and 12 cts., not the highest nor even the lowest quotation, of white comb honey, but 2 cts. below the lowest for the price of comb honey.

Your second error appears in your valuation of the sections which were given to the bees to finish. You say they ought to bring 8 cts.; but, consider that in five cases 140 of them weighed but 41 lbs. less than one-third full, and you will see that they are not only not salable but actually worth less than extracted honey for the purpose of extracting, on account of the labor and loss in weight that must be incurred if that course is taken with them; so I have put them at 6 cts., when 7 cts., the highest price of extracted honey, is taken; but when the lowest price, $5\frac{1}{2}$ cts., is taken for extracted, I have let the sections go in at the same price.

Now, taking the figures of the same hive which you considered, let us make the calculations, both with the highest market and the lowest market prices, and see how far I was wrong when I said the profit was more than 50 per cent.

41 lbs. sections at 6 cts., \$2.46; 106 $\frac{3}{4}$ extracted honey at 7 cts., \$7.48; a total of \$9.94; 110 $\frac{3}{4}$ lbs. finished comb honey at 16 cts., \$17.72. Dividing \$17.72 by 9.94 we have a quotient of 1.78+, showing a profit of 78 per cent.

Again, taking the lowest market prices we have 147 $\frac{3}{4}$ lbs. given the bees at $5\frac{1}{2}$ cts., \$8.13; 110 $\frac{3}{4}$ lbs. comb honey at 14 cts., \$5.51. Dividing \$15.51 by 8.13 we have a quotient of \$1.90, or a profit of 90 per cent. So when I said 50 per cent, I might reasonably have put it 50 per cent higher, unless there is something valid to be found in the further objections you make. You think the labor of feeding would largely offset the 23 $\frac{1}{2}$ per cent gain you figure. But, notwithstanding what you say, will not the improved condition of the colony more than offset the labor? I think so. I do not know how much this hive gained in weight; but in my experiment, made in 1893, seven colonies gained on an average about 8 $\frac{1}{2}$ lbs., which alone would repay the labor. Then you object to the greatly increased amount of brood as being probably of no use. Consider at what time of the year this additional brood will hatch—in the latter part of August and the first of September, just when they are wanted to get the colony through the winter in the best possible condition. In my estimation this would pay for the labor again.

You are of the opinion that, in my experiment, the conditions were more than ordinarily favorable. In fact, they were quite the contrary. The colony was far from strong—hardly up to the average—as at no time during the season had it more brood comb than the equiv-

alent of five L. combs. No attempt was made to do a great thing, but only to show what could be done under very ordinary circumstances. Then another adverse circumstance was the fact that the unfinished sections contained much less honey than would ordinarily be the case—a fact that would seriously reduce the apparent profit.

It can be hardly be seriously claimed that Mr. Unterkircher's experience furnishes a case in point. It was clearly a case of gross mismanagement for which there was no kind of excuse. Whatever his intentions were, he evidently permitted the bees to store the honey fed in the brood-chamber.

Lapeer, Mich., Feb. 4.

[I fear I shall have to eat humble pie a (just) des(s)ert I don't like. My only excuse was carelessness in looking over the market reports, and I am the more sorry that they appear to favor my position. It was unintentional, however. My eye must have dwelt too long on the California reports of the previous number.—ED.]

THOSE STRAWBERRIES.

A POINTER.

By M. Dea.

Blamed if I don't believe Bro. A. I. Root's a crank—just like me—on the subject of strawberry culture! Just about the full o' the moon at this season of the year the fit comes on—lie awake o' nights thinking just how and what kind to plant. I rather think the hill system is yet the best all-round method, every thing considered, and that the Timbrell, take 'em all in all, is about as good a berry as any—not but that other kinds do excellently, and really should be a part of the patch, if for no other reason than help fertilize it thoroughly; but, you know, we've all got a particular fancy for some kind.

But this must be considered: Strawberries are powerful pesky things to disappoint a fellow just when he doesn't want any foolishness. You hear of a certain kind that Bro. Jones has, that he says bears so and so many quarts to the square rod. It sounds pretty big—heaps o' money and lots of fun in those berries. Bro. Smith resolves to have a half-acre, even if it costs his muly cow. Oh, yes! the plants come on—look fine; has his land just so—as recommended: gets Mandy (that's his wife) and Liza Jane to come over to help set the plants, and they nearly break their backs; and, there! now all those berries have to do is to get right up and hump themselves to produce the stuff that sells at big prices for small quarts. That's it. Hang up the old tin pans, and make awful-looking scarecrows to keep the birds off that patch; and, Mandy, be sartain to shoo off the chickens and the boys.

June comes along finely; the plants look perfection; leaves like spinach, almost; buds a

startin', big as buttons on Liza Jane's winter coat: yes, right down blossoms, or I'm a hen. Well, well! now that's what I call big luck. Rushy Ann! Why, that means a big sum in our county bank, sure. Now let me see—40 and 39 carried several times is so much, and so many of the last picking is so much; in all—Riah Jane! hoopie! whew! Why, there'll be 'nuff money left, after paying the mortgage, to buy the old lady and darter each a fine dress, bonnets, and folderolls. Oh! I'm smart, I am! Honey and slap-jacks! What ails them meechen things? In a week the whole passel of buds and flowers has shrunk—actually turned yaller, and in July there aren't berries enough to make a respectable shortberry strawcake! That was the beatenest swindle!

No, it wasn't. The man you bought your plants of was all right—in *New Jersey*; what he said was so too; but his land is different—more gravel; yours is all rich loam, and that makes a world of difference in results. So you see the kinds that do so well on a special soil will hardly fruit at all on some others. Sabe?

THE DOVETAILED CHAFF HIVE.

FOWLS' IMPROVEMENT.

By Chas. Fowls.

I send you by this mail a photo of the Dove-tailed chaff hive with some improvements which are new only in their adaptation to the Dovetailed chaff hive. One thing I really felt the need of was handles. They should be made by nailing strips on the hive $\frac{1}{2}$ or $\frac{3}{4}$ inch thick by one inch wide by 4 or 5 inches long. I prefer them in the middle of each end, and one inch below the water-table. If you ever try to move one of these hives when filled with bees and honey I think you will appreciate handles. There is no reason why these hives should be any more clumsy or inconvenient than the old style Langstroth, which they very much resemble. One of the conveniences of the old-Langstroth was the entrance-blocks. I've been bothered a good many times in the last dozen years in closing the entrances of chaff hives. Sometimes robbers would commence on a weak colony, then I must hunt for a stick. If too long or too thick it must be whittled; if too short or too thin, I must hunt another, the rascals all the while piling into the hive.

A 2x2-inch piece should be nailed on $\frac{1}{2}$ or $\frac{3}{4}$ inch below the entrance, so water will not run into the hive. Being 2 inches thick it makes a good alighting-board, and the front side is left rough along in the middle so they can stick

their toe-nails in to climb up, if they should bring in such "dead loads" as to fall short of the entrance (which provision was entirely unnecessary this year, as a gimlet-hole might have answered for alighting and entering). The three-cornered block formerly used for an alighting-board is sawed in two to make entrance-blocks, sawing a little piece out of the middle as shown in the picture. It is shown

nearly closed, as used to keep out robbers. But the most important feature is the tray to hold the top packing. The chaff cushion is all right for the old-style chaff hive. The old chaff hive admits of its being tucked down snugly in the corner so as to prevent drafts, yet secures perfect ventilation up through the middle of the chaff, because all dampness can pass off at once, owing to the space between the cushion and the roof. Now, this requirement is not met with the cushion in the Dovetailed chaff hive. The inside of the cover will become wet and moldy, as also the cushion. This tray secures all the conditions connected with the use of cushions in the old-style chaff hive.

Ten years ago I visited Mr. J. S. Hill, at Mt. Healthy, O. He is the author of the Hill device. I visited a few days with Mr. Muth, and he told me I must not fail to go to see Mr. Hill, as he had the best-kept apiary in the State. When I saw it I concluded Mr. Muth was not far out of the way. He had a hundred or more colonies in Langstroth hives; no grass was permitted in the apiary, but he had a stalk of flax to shade each hive. This was in the fall, and he was just cutting down the dead stalks. Each hive was provided with a Hill device and tray. I did not notice how his were made, but I'll tell how I made mine. Either the sides or the ends should be 6 inches high, so as only to let the cover telescope over the rim-piece one inch. I made the sides from the crating the hives came in. The ends should be short enough so the sides can be nailed on to them, and leave the tray $\frac{1}{4}$ inch less each way than the inside dimensions of the cover. The boards for the ends should be sawed off perfectly straight, otherwise the tray will be diamond-shaped, and the cover won't slip on and off freely. It would be better to have the ends cut at the factory, as it bothers "some folks" to saw a board off accurately.

To cut the burlap for the bottom, spread it out, and, taking the tray for a guide, cut an inch larger all around. To nail on, lay on a table or bench; put the burlap in with the edge sticking up in the inside, and fasten with thin strips, say $\frac{1}{4}$ by 1 inch, clamping the cloth fast. It takes but a few nails this way. A brick laid under while nailing will make it loose enough to cover the Hill device, or whatever is used across the frames for a winter-passage.

For packing I shall use maple leaves for the tray, as they are easy to get—no grain mixed in to entice the mice to make nests, etc. In the spring they may be thrown away and fresh ones got in the fall.

While discussing the matter of hives, I wish to call your attention to a point I mentioned to you three or four years ago. I told you that your flat covers for the Dovetailed hives were too thick. Mine were only $\frac{3}{8}$ and $\frac{1}{2}$ inch thick. You were afraid the thin cover would warp worse than the thick ones. Well, after having had an opportunity to compare them since then, I want to repeat what I said then, that the thin cover will not warp or wind nearly as much as the thick ones. You see, there is not as much wood to strain on the end pieces, which are just as heavy as those on the thick ones. In proof of this I will say I have covers only $\frac{3}{8}$ inch that I have used at least ten years, that are still as straight as ever. I don't think I should like the Higginsville cover as well as these.

Oberlin, O., Dec. 1, 1894.

[The tray may possibly give better results than the simple cushion; but as we have had good results with the latter, we have given it the preference in our catalog. The tray, if made of rough three-eighths crating, would be cheaper than the cushion, and would be easier to pack. We do not as a rule ship the hives with cushions, as each bee-keeper is supposed to fix up for himself what he likes best. I commend Mr. Fowls' arrangement. About that three-eighths-inch cover, I should like to hear from others who may be using them. I have been afraid that they would check.—ED.]

LAYING CAPACITY OF QUEENS.

Question.—I see that very many of our most practical apiarists are recommending eight Langstroth frames as the right size of brood-chamber for a strong colony of bees. Such eight-frame Langstroth hive, if entirely occupied with worker comb, contains 1168 square inches of comb, or about 58,400 cells. From this we must deduct at least 10 per cent of the space for the usual supply of honey and pollen, leaving about 52,500 cells. Allowing 21 days for the bee to hatch, and one day for the bees

to fix the cell and for the queen to lay in it again, we have an average of a little less than 2400 cells for the queen to fill per day. Now, is 2400 eggs the utmost daily laying capacity of a queen in a strong colony? and if not, should any queen be restricted to that amount when she could and naturally would lay more? I ask these questions to help me determine what size of hive to build this winter, having up to this time supposed that a ten-frame L. hive was the smallest hive that could be profitably used.

Answer.—If a colony of bees having a good prolific queen is given 30 Langstroth frames, using but 8 to start with, and adding two or three at a time, as the bees can occupy them, until the 30 are all in, it will be found that such a queen will lay from 5000 to 6000 eggs daily, during the best part of the egg-laying season, and die of old age or exhaustion when but 18 to 24 months old; while with the 8-frame brood-chamber she will give as good results in comb honey, if not better, each year, and live for four or five years. I take it for granted that our questioner is a comb-honey producer, although he does not say so, and shall give my views of the matter wholly along that line. With the large hive the bees are quite likely to get the start of the queen, and commence to store honey in the brood-combs before entering the sections at all, and in such a case the bees seem loth to go into the sections, and continue to store honey in the brood-chamber in preference to going into the sections, thus crowding out the queen with honey in the comb which ought to be occupied with brood, till we have as a result very little section honey in the fall, and a colony in poor condition for winter. Besides, it is well to remember that all queens are not equally prolific; and while 20 per cent of our queens would keep the brood-chamber of a ten-frame Langstroth hive properly supplied with brood to give the best results in section honey, the other 80 per cent would not be prolific enough to do so; hence in the majority of the hives in the apiary we should have a condition working against our best interests, which could not be overcome by the extra amount of comb honey produced by the 20 per cent whose queens were prolific enough to work in these ten-frame hives to advantage. For these reasons it would seem best to adopt a size of brood-chamber which any and all queens, which were worth keeping at all, would have occupied with brood at the commencement of the honey-flow, thus securing the best yields of surplus section honey at all times. Because a queen may lay 6000 eggs daily by using plenty of comb capacity and coaxing, it does not necessarily follow that it is to the best advantage of the apiarist to accommodate or even coax a queen to bring her fullest laying capacity to the front at any time. Queens, in any well-regulated apiary, are among the

smallest part of the expense incurred, while labor, hives, and combs go toward making up the larger part of the same. For these reasons, I claim that the capacity of the queen should rather be above the capacity of the brood-nest than below it, so that all combs may be fully occupied with brood. Unless this is the case the outside combs continue, in most cases, to be dead capital from year to year, unless we argue that they are necessary to insure the safe wintering of the bees. After an experience of over 25 years, I can not consider any argument along this insurance line as aught but fallacious.

Again, suppose that a queen can average 5000 eggs daily for a certain period. What is the price or worth of those eggs? Does the sum and substance of bee-keeping depend on keeping all queens employed at egg-laying to their fullest capacity? Bees, when they come on the stage of action at just the right time, are very valuable; but eggs are of no value, only as they tend in the direction of producing these valuable bees. Aye, they tend toward a positive disadvantage, and to take away the value we already have, only as they are looking toward the end of producing the required bees in the field at the time of the honey-harvest. Here is a point often lost sight of by the large-hive advocates. As I said before, eggs cost practically nothing; but as soon as the bees begin to perfect them toward bees, then they begin to cost; and if this perfecting is going on to any great extent at a time when the perfected product is placed on the stage of action either before or after their presence in large numbers is needed, we not only have the cost of their perfecting to pay for, but the cost of their consuming, after being perfected, as well. This consuming part, we always have to pay for; but we willingly do it at any time when the production of the individual bee is greater than its consumption. But I can see no object in doing this at any other time, simply that the extra laying capacity of any queen may be gratified. A hive that is large enough to gratify the greatest aspirations of very prolific queens, at the times of these greatest aspirations, will have too much capital lying idle in it the largest share of the year, and be a bungling hive at that. From all past experience I think that 2400 eggs per day would be a good maximum average for any queen. Rain, cold, or other disturbing influences often retard the activity in the hive and of the queen, and thus it happens that at times the best of queens often do not lay more than 1000 eggs in a day, while, with the right conditions, she may multiply this number by four, and still have plenty of room in a hive which will give an average of only 2400 daily. Then, again, as two and one-seventh generations of bees can be brought on the stage of action to where one steps off, we find that, in a hive giving an average of

2400 bees daily, we can have in that hive, if properly managed, 108,000 bees on the stage of action right in the honey-harvest, when their productive power is the greatest; and at such a time such a number of bees are a host to roll honey into the sections with the combs all filled with brood below; and this rolling of honey into the sections, means the rolling of money into the bee-keeper's till. Experience has shown these men who are advocating an eight-frame L. hive that such is the best, as this keeps the frames full of brood, and puts honey into the sections. However, all our questioner (or any one else) has to do is to use part ten-frame and part eight-frame hives in their apiary, when a little time will satisfy them which is best.

In order to make a symposium on the subject of bee-paralysis, we have concluded to hold over Mr. Baldensperger's article, which we promised for this issue. A valuable one on the same subject will be given from the pen of Dr. J. P. H. Brown, of Augusta, Ga.

THE editor of the *Review* echoes the same thought that has come to me at times regarding the value of other bee-journals besides our own. He says:

Apicultural literature was never better than it is to-day, and this in the face of about the hardest times financially and apiculturally that we have seen in a long time. As journal after journal came in for December, all bright, fresh, well-printed and illustrated, and crammed with interesting and helpful articles, I fell to wondering if my own journal appeared as attractive to the other editors as theirs did to me. If it did I am satisfied. Bee-keepers have every reason to be proud of their literature.

"HONEY-BEE CONCERT" is the title of a leaflet gotten out under the auspices of the Ontario Bee-keepers' Association. It took place on Wednesday, Jan. 23. Its object was purely educational, designed to bring in outsiders. I have no doubt it was a grand success. The following is the program that was laid out:

1. Instrumental duet, Mrs. Scarff and Mrs. Bruce.
2. Address by President A. Pickett.
3. Quartette, Misses Mark and Eason, and Messrs. Irving and Hepburn.
4. Solo, Mrs. Stone.
5. Address by Hon. John Dryden.
6. Solo, Mr. H. F. Gadsby.
7. Recitation, Mildred Gemmill.
8. Magic-lantern exhibition and lecture, Mr. R. F. Holtermann.
9. Violin solo, Mr. R. W. Roberts.

It could hardly fail to be entertaining and educational. The scheme is a good one, and I hope it may be repeated in some form at the next N. A. B. K. A., to be held at Toronto.

D. A. JONES, PAST AND PRESENT.

I LEARN from the *Canadian Bee Journal* that one of the factory buildings (the largest) of the former D. A. Jones Co., Limited, went up in fire on the 30th of December last. Beeton has been very unfortunate in its fires. The office of the *Canadian Bee Journal*, founded by D. A. Jones, was burned out once, and now virtually all that remained of the once large supply business with it is gone also. The building was used for other purposes, and was owned by Dr. Cheffy at the time of the fire.

By the way, where is our genial friend of old, D. A. Jones, whose fame shot forth so like a meteor? There was a time when he was the leading bee-keeper of Canada, the leading bee-editor, the leading supply-dealer, a leader in apicultural thought, and a man known the world over. He traveled over the Orient, and spent thousands of dollars in the pursuit of new races of bees, and later established queen-rearing on islands of Georgian Bay. While we remember him for his brilliant past it would be a pleasure to know something of his present, even though not a bee-keeper now.

THE PRESENT WINTER, AND WHAT IT MEANS TO BEE-KEEPERS.

In our locality we have not had for years such prolonged and severe weather with high winds as we are now having. We scarcely ever have more than ten days or two weeks of cold weather, and then we have a thaw and a few warm days. But up to date, Feb. 8, our bees have not had a flight since Christmas. Indeed, the mercury has scarcely been up to the freezing-point. For the past four days it has been hanging, both day and night, close to zero—scarcely varying a degree one way or the other; and, more than this, there are high winds. I am well aware this is not cold compared with some localities. Indeed, Dr. Miller says, in the first *Straw* in this issue, that his thermometer showed 23 below zero on the morning of the 5th; and I doubt not it has been very much colder in other northern localities. Well, then, if this winter is so much colder than former ones, which I think it is, it is going to be a terribly hard one on bees, for bee-keepers have a habit of preparing rather for mild winters than for severe ones. The result will be, unless I am very much mistaken, and unless the weather moderates considerably, that there will be severe winter losses, and, as a consequence, there will be discouraged bee-keepers with a lot of supplies on hand, perhaps unpaid for. But it is the outdoor colonies that will suffer, I fear, and particularly those that have not been put into double-walled hives or winter cases. I do not wish to forebode calamity; but I think it would be well for bee-keepers to consider the possibility of their losing heavily, and therefore not requiring the supplies that might otherwise be needed. I am well aware that this

may chop off some of our orders; but I think it is only fair for bee-keepers to be properly on their guard.

Now let us turn to a more encouraging view of the situation. Cold winters, accompanied with snow, as is this winter, are said to mean an abundance of clover; and that, of course, means honey. The moral is, *save* your bees and get the honey.

BOGUS HONEY.

The following letter will explain itself:

Friend Root.—The attached letter was received by me in answer to an advertisement for a situation as stenographer or book-keeper. As it seems to settle a number of questions in regard to bee-keeping, I thought it might interest you. The "king bees" had better get together and form a trust or they will soon find their occupation gone. W. HICKOX.

Lakewood, O., Feb. 2.

And here is the letter referred to. It is very evident that Mr. McCarthy got hold of the wrong man. It is a little surprising that he should "give himself away" quite so bad.

Box 108, Lakewood, O.:

Dear Sir:—Do you care to take an interest in a good paying business? I have an article whose merits are unequalled in the markets: it is manufactured honey, made from the oils and extracts of flowers that the bee gathers its honey from. I put it up in 1-lb. jars, labeled and sealed ready for the market, at a cost of 7 cts. per lb. It retails at 20 cts. per lb. I am a poor man, and have to work for my living. I have not got the money to go ahead with, and want some good honest man to take one-half interest and help me put the goods on the market. This is a good chance for the right party; so if you do not care to investigate, perhaps you have a friend who would. I have explained the best I can at present. Hoping to hear from you soon I remain

Respectfully yours,

1732 St. Clair St., Cleveland. W. J. MCCARTHY.

I thought best to give our readers the contents of the letter from Mr. McCarthy. I do not know certainly whether he intended to put this manufactured "stuff" on the market as pure honey or not; but the presumption is rather that way. Mr. McC. says he is a poor man and wants some good honest man to take an interest in the business. Honest man! it would be hard to find one who would engage in that business—that is, *providing* he proposes to sell bogus honey for the pure. If any of our readers in Cleveland are located where these goods are sold they will oblige us by giving the particulars.

ADVANTAGE OF CHAFF HIVES IN THE CELLAR.

We have generally supposed that single-walled hives were plenty warm enough for cellar wintering; that to put *chaff hives* in such a place was both an unnecessary expense and a waste of cellar room, to say nothing of the work of toting these unwieldy things, full of bees and stores, up and down steps back and

forth. Notwithstanding it looks like wearing an overcoat in the house. Doolittle has decided (see *American Bee Journal*) that it *pays*, both in the saving of stores, and the better condition of the bees. This conclusion he has reached after some carefully conducted experiments, and now not only seven-eighths of all his colonies are in chaff hives, but three-fourths of them are in the cellar. His chaff hives have loose bottom-boards, and are raised up from the same while in the cellar by blocks of stove-wood. In summing up he says:

I have just been in to see them, so that I might tell the reader the difference between these and those in single-walled hives. Those in the single-walled hives are clustered closely on all parts of the cluster—bottom, top, and sides—the same as they would be outdoors, only not quite so completely; while those in the chaff hives are clustered just as closely as the others at the bottom of the cluster, and a little way up the sides; but as you come toward the upper half of the colony, the bees stand out around the combs the same as they would in summer; while at the top, all along next to the cushion and cotton cloth, they make no pretension at clustering whatever, although you can look at them a long time without any of them stirring, no matter how close you hold the light to the hive. In this way they have free access to all parts of the hive, so a colony never starves, so long as there is any honey in the hive, by their eating the honey from one side and falling to move over, as is frequently the case.

But the greatest item of the whole is, that these colonies in chaff hives do not consume nearly as much honey as do those in single-walled hives, while the safety of their wintering successfully is more fully assured; for the less honey consumed by a good colony of bees insure their more perfect wintering. Where hives are wheeled right into the cellar, as I do mine, the labor of putting them in is little more than with single-walled hives, and this labor question is all there is against the matter, except that a less number can be put into a given space; and the saving of honey will, I think, more than compensate for the extra room needed, and pay for building a little larger, where it should be necessary.

I am inclined to think Doolittle is right. At all events, it would be well for a few others to try the same experiments. If you have any double-walled colonies out doors that look as if they would go up before spring, put them in the cellar now. But, say—it occurs to me that the great majority of the makes of chaff hives, perhaps all of them, have tight bottoms. Colonies in winter cases can be so tried at all events.

FIVE-BANDERS RECEIVING MORE HARD KNOCKS FROM BEE-EDITORS.

THE editor of the *Canadian Bee Journal*, after stating that he is as anxious as any one to have bees which will give large yields of honey, which are easily handled, and which have beauty, says this:

Were we to engage a man or maid to perform our work simply on account of looks, it would be

better for us to give up business or for our friends to lock us up in a lunatic-asylum. We think it would be well for bee-keepers to examine themselves and see what leads them to be favorably impressed with the "five-banded Italian bees." Is it not their beauty? Should they not rather regard that as very secondary, and look for the primary requisites before launching out in eulogies? We have tried various five-banded queens from what were supposed to be the leading breeders of these bees. They have thus far done nothing remarkable in the direction of good works, whatever they may do during the coming season. Thus far we have not found them particularly good for building up—rather to the contrary. Next, although they showed no marked trait when in a normal condition, we have found the workers in two instances, being every instance in our case, very irritable when in that condition. We remember a queen secured from a lady in the South in the fall of 1893. A good big price was paid for the queen, and also a second purchased. Although going into winter quarters strong in bees it was in poor condition in the spring, and was on only three frames when the next poorest was on eight. After a great deal of trouble, and the refusal on our part to add another \$5 to the returned queen and get a "first-class," we had the offer to give us a \$5 queen at half the price of the first. This we accepted, and the queen came to hand, with the admonition that, for \$5, the progeny would not be all five-banded. They can not, therefore, be considered a very fixed strain of bees.

Last year the Ontario Agricultural and Experimental Union took in hand to make tests with these five-banded Southern queens. Five queens of the leather-colored Italian strain were also supplied—in all, 25. The queens were supplied between July and October 2, and they are to be tested for gentleness, longevity, honey-gathering qualities, etc. Thus far every one having the leather-colored Italian and the five-banded Italian, without soliciting this fall a reply in this direction, mentions the superiority of the leather-colored queen as to prolific qualities. Four of the five-banded queens have already been superseded, which does not speak well for their longevity; several were also lost in introduction. We notice that the Vermont bee-keepers are, at their coming convention, to discuss whether it is advisable, in view of the prevalence of bee paralysis in the South, to purchase queens from there. If those wide-awake Vermont bee-keepers begin to doubt the wisdom of such purchases, the rest of us may well hesitate. Let us not add another disease to battle with.

I also notice that Editor Leahy, in the last *Progressive*, pays his respects to them in this fashion:

I have never received a so-called "five-banded" queen from Mr. Doolittle, but 4 or 5 years ago I ordered one direct from Mr. Hearn, paying him \$3.50 for her, this being his price of tested queens. This queen produced the most worthless, and at the same time most vicious bees that I ever had any experience with (hybrids not excepted), they being small, with a black shiny spot at the end of the abdomen. The following winter they dwindled away and died on the summer-stand, yet they were packed in sawdust. Since then I have ordered five-banded queens from a number of other breeders with some very good results and some very bad.

Editor Alley, in the *Apiculturist*, has been giving those golden fellows "regular fits." Editor Hutchinson, in the *Review*—well, I can't find where he stands, so I'll put him on the fence, and Editor York beside him. I have been on both sides of the aforesaid fence; but I have stayed longer, and on the side of the opposers of the yellow fellows; indeed, I feel more inclined to stay there because the majority of the testimony seems rather to be against them (the yellow bees).

OUR RELIGIOUS PAPERS AND ELECTROPOISE.

We copy the following entire from *Electricity* of Jan. 9, 1895:

There can be no defense. The publications accepting that advertisement confess a willingness to make money by aiding a swindle. Yet the *Churchman* has the hypocritical effrontery to descant upon the evils of the Sunday newspaper:

"The discussion of the Sunday newspaper at the Church Congress gave much satisfaction to Christians interested in the preservation of the brief hours of the Lord's Day for the development of the spiritual nature of man; and the words of the more seriously minded of the speakers were uniformly devoted to impressing upon churchmen the inevitable loss sustained by those who either neglect divine worship for the attractions of the Sunday newspaper, or attend the services of the church with minds and hearts indisposed by such reading, to receive their hallowed influences."

The evils of the Sunday newspaper, however great they may be, would better be pointed out by some paper like the *Sunday School Times*, the *Christian Advocate* of New York, or the *Western Christian Advocate* of Cincinnati, papers whose advertising space is not for sale to promote a fraud, and which can at least come into the discussion of a moral question with clean hands.

We do not know how many other religious papers are still carrying the Electropoise advertisement, but the stain of dishonor and corruption rests on every one of them.

The moral is so plain that we need not add any thing. However, I wish to call attention to the excellent recommendation they indirectly give our old friend the *Sunday School Times*, in the above.—A. I. R.

CORRECTIONS.

On page 110, the senior editor, in speaking of the cement pavement used in Jacksonville, meant to say that it is a sort of limy *marl* instead of *marble*. He says his amanuensis wrote it marble, and that he is sure he corrected it; but there it stands, as plain as print, without a mark on it, *marble*. On page 111 he meant to speak of the children as being *neatly* dressed, and not *mottley*. There being no loop in the top of the *e*, the word looks just like *motty*, and we supplied the last *e*, thinking he had omitted it by a slip of the pen.

A. I. R. is again writing on the subject of bees (see this and next issue), with his old-time enthusiasm, of what he sees in Florida. I speak of this because he has not written on apicultural matters to any extent for a number of years. His writings have been confined largely to general subjects of travel, gardening, and things that pertain to our general conduct and its relation to heavenly things.

OUR RAILROADS AND RAILROAD CORPORATIONS.

It is so common to hear complaints in regard to our railroad companies that it may sound a little odd to say a word in their favor. So far in our experience, however, we have met nothing but the kindest courtesy. My wheel was laid down here in Jacksonville without a bit of expense. Of course, we checked it as baggage, and our luggage was laid down at our rooms at a very trifling expense. Porters were gentlemanly and exceedingly obliging. I met one of them on the streets of Jacksonville after I had been here a day or two, and I was really glad to shake hands with him, even if he is colored. By the way, I have heard people speak of the insolence and exorbitant charges of the waiters here in Florida. So far we have seen nothing of the kind, but quite the contrary; and I have been wondering if it is not true that education is beginning to tell on these people. I have been studying them, their ways and habits, very intently since we came here, and I think I can say this: They not only seem to be exceedingly good-natured, cheerful, hopeful, and full of spirits, but they are, as a rule, industrious working people. Quite a little excitement has been occasioned among them by the advent of the Dahomey Village that appeared at the World's Fair. They have a tent here, and have a street parade during the day. The enthusiasm among their own people here in Jacksonville is almost wild. A circus or show entirely in the hands of full-blooded Africans from their own country is to them an event unprecedented. These native Africans are models of physical health and development. There seems to be a pretty sharp line drawn between the colored people and the whites in this city. Where they do business back and forth, each race seems to keep within certain limits; and I am told intermarrying and amalgamation is comparatively rare.

When I explained to the different railroad officers here where I wanted to go, and told them what I wanted to do, they were more obliging than I had any reason to expect; and not only in the way of giving me full directions and assistance, but in making very reasonable charges.

IN SAN MATEO.

This morning we are at A. F. Brown's beautiful ranch. The most conspicuous object on the grounds is the magnificent great live-oaks with their spreading branches draped with festoons of Spanish moss; in fact, nowhere else in our travels have we seen either, in such wondrous perfection. It is our pleasure to meet here two bee-keepers of considerable prominence—V. V. Blackmer and Chas. D. Duvall. Mr. Blackmer has been associated with friend Brown in his bee-business; and friend Duvall, the queen-breeder, is assisting friend Brown, and raising queens for himself. There is a point right here, friends, that may be worth while to consider. After a bee-keeper away up north has his bees safely put away for the winter he can come down here and have lots of fun, and, may be, do some good by following his chosen pursuit all winter long. The principal drawback is the expense of so long a trip; and I hereby petition the railroad companies to make a low-rate round-trip ticket especially for bee-keepers to come down, say in December, and go back about the first of April. It would be a comparatively easy matter, it seems to me, for

a hundred bee-keepers or more to club together and send in a petition before next winter. GLEANINGS and the other bee-journals will, without doubt, help it along, and may be we editors could take a trip down and look the boys over and see whether they behaved (went to meeting Sundays, etc.), when their wives were not around—that is, providing said wives did not go along.

Now for the oaks and moss: One great oak right close by the house—in fact, it shades quite a part of the extensive verandas—has great spreading branches that actually measure from "tip to tip" something like 90 feet. Imagine a large symmetrical apple-tree occupying a circle nearly 100 feet across, and every limb and branch draped with delicate lacework of this beautiful moss. Now imagine these long tresses rippling in the wind like the soft flaxen hair of a playful child.

Our friends mentioned have just been transferring bees from box hives and log gums into the latest pattern of improved hives, sent by carload lots from a place away up north, where a lot of Roots, old and young, work together to fix out bee-keepers down south and elsewhere. Perhaps you may be surprised when I tell you that these friends, in transferring bees, have actually made thirty-two in a day. The new hives under the waving mossy trees present a very pretty view indeed. We are promised a picture of it.

MIGRATORY BEE-KEEPING IN FLORIDA.

Friend Brown is making a specialty of migratory bee-keeping. He usually gets his first crop of honey here from orange, then he transports his bees by boat and rail to New Smyrna, or some place on the coast where his bees can get palmetto honey; then he goes to the mangrove regions on the coast, but ten or twelve miles from the palmetto country. After this he takes in the yellow-partridge peas on the pine lands of the interior; next he gets honey from wild goldenrod and sunflower on the prairie river-bottom lands, making four or five crops in a year. A single colony thus transported by way of experiment, gathered last season 576½ lbs. of honey; and an entire apiary (he says) can be made to average from 260 to 350 lbs. Mr. B. has made 16 moves in four years, with only two failures. Of course, much judgment and skill must be exercised in deciding when and where to move. He has kindly given us the following list of sources of honey which can be reached within a radius of from forty to sixty miles: Pennyroyal, December to February; orange, February and March; tyty, during March; tupelo gum, March and April; palmetto in May; mangrove in June and July; cabbage palmetto, July; yellow-partridge pea, August; goldenrod, September; sunflower, and goldenrod of another species, in October and November; maple in December and January; gallberry, March and April.

In this vicinity are acres upon acres of the most beautiful orange-orchards I have ever seen in my life; and at the present writing the ground is literally yellow—yes, sometimes heaped-up yellowness—with frosted oranges. Many fears are indulged in that the trees, at least many of them, are killed as well as the fruit. Of course, all the orchards are not up to such a standard of perfection as I have mentioned; and upon asking why one orchard showed such luxuriance of growth while the one adjoining was dilapidation and ruin, I was told it was all in cultivation and fertilizers; and our well-known northern brands, say the Bradley, Bowker, Mapes, etc., are being used largely with excellent results. I am very glad indeed to know this. I was curious to know whether the Florida rock phosphates were also used

here, but I am told they are not much used—at least in this locality.

There is no gardening going on around here; in fact, we have seen nothing I could call gardening as yet in Florida—hardly so much as a bed of onions, lettuce, or radishes; neither is anybody planting potatoes, notwithstanding the fact that Irish potatoes shipped from the North bring 40 or 50 cts. a peck! neither does any one keep a cow and pig, as we people do up north, and yet milk is 10 cts. a quart; eggs, 25 to 35 cts. a dozen, and other things accordingly. I have several times suggested having potatoes shipped direct from expert growers up north; but people here mostly buy a peck or so at a time; and it takes so many "middlemen" to get a carload of potatoes into the hands of the consumer that the expense would bridge over the difference between 50 cts. a bushel and 50 cts. a peck. Notwithstanding, I am sure there is an opening here, for both sweet and Irish potatoes are on the table at almost every meal, and I for one should like the fun of selling milk for 10 cts. a quart. If I couldn't get alfalfa or some other plant to furnish cow-feed it would be funny. I asked one of the milk-men, as he was going his rounds, what they fed their cows down south. He looked at me for a moment just as if he thought I was a meddlesome, no-account Yankee; but he finally answered in a sort of surly way, as he turned his back to me, "Cotton-seed meal and bran." Now, look here; why can't somebody get that cheap wheat and corn that comes from Missouri for 35 cts. a bushel, you know, down here, and convert it into milk at 10 cts. a quart? Why, there is a gold-mine in the speculation. You see, you don't have to lay out a great deal of money in frost-proof stables. Mr. Brown said a wire fence around the outside, and a cotton cloth for a tent-like cover over the top would be all the stable the cows would need.

Oh! just a word more about the moss. Friend Brown says it is an air-plant, and the only reason why it is found on the trees is that it wants a place to hang on, up in the air. He said it would grow just as well hanging across a wire fence as on a tree; but friend Blackmer says it isn't so. Mr. Blackmer is old and gray-headed, like myself, and knows a lot more than these young chaps, even if they have lived in Florida all their lives. I have a private speculation of my own, that perhaps we might feed the cows on the moss—that is, we would have the moss take the place of hay while we were feeding them on corn meal and bran.

THE PICNIC ON THE RIVER.

Bee-keepers are geniuses, as I have often said before; especially are the successful bee-keepers men of mechanical and scientific attainments. Friend Brown has an electric gasoline launch for running about on the river. The boat is only 21 feet long, and it is worked by a $\frac{1}{2}$ -horse-power engine. To-day it pulled a string of three boats, loaded with picnickers. When I first saw the crowd that was to go, I feared the little launch would hardly handle them all; but it took us some eight or ten miles and back in fine style, I tell you. I think I never enjoyed a picnic more. The thing that added to my enjoyment was that I had a place close to the engine, and was enabled to study carefully its working. Almost twenty years ago (in fact, it was at the Centennial Exposition, in Philadelphia) I first saw a gas-engine. In this first crude affair the gas was exploded by a burning jet, and it sent the piston away up with a tremendous explosion. The modern machine occupies very little room for the power it generates; in fact, the *cylinder* is about the principal part of the machine. A small quantity of gasoline, measured out exactly for the

work required, is turned to vapor, then mixed with the proper proportion of atmospheric air to produce an explosive compound. This compound is fired in the cylinder by an electric spark, and the force of the explosion gives the power. It seems almost incredible that all this could take place at each stroke of the piston when the engine made as many as five revolutions *per second*. I enjoyed most heartily every rod of our trip after I had the hang of the machine enough to see how it did its work. It really propels the boat by a series of "kicks"—yes, vigorous kicks—and the kicks are at the rate of five a second. Where is the kicker who can beat that? Now, mind you, besides this it occupies such a very small space that it can not possibly blow up, because it really *does* blow up five times every second—that is, all it *can* blow up. There is no boiler, and no reservoir of any thing but gasoline, and this is away off at the other end of the boat. Great precautions are taken to prevent this reservoir from letting loose the gasoline any faster than the engine uses it. By great carelessness the gasoline pipe *might* be broken so as to let the dangerous liquid out into the boat. Then if some one should throw a match into it, it *might* burn. But even in such a case, as the boat is always in the open air there could be no real explosion. The occupants might get their clothing set on fire; but all they would have to do would be to climb over into the water and let themselves down until the fire was out.

While I was enjoying seeing the thing work, I could not but reflect on the amount of brains and hard study that had, step by step, during these twenty years past, conquered obstacle after obstacle, and brought the machine to its present state of perfection. In fact, it seems almost impossible that any really valuable invention can come about in any other way. Not only must one man make it, perhaps, a life study, but other men, and often succeeding generations, work out these great triumphs of human intelligence over the forces of nature.*

By the way, friend Brown proposes, if I am correct, to make this gas-engine launch help him in his migratory bee-keeping. You see, he can put a pretty good-sized apiary on a cheap raft, or lighter, and then this little giant of strength and power, this compact "genii" of boiled-down power and energy, will take the whole apiary and fairly make it skim over the St. Johns River and tributaries, to any point where honey may be coming in. We just had the nicest crowd of boys and girls, in my opinion, to be found in Florida, or any other land; and let me say to you confidentially that Mr. Brown's little sister, who presides over his housekeeping affairs in a model fashion, is not one whit behind the rest of the crowd; and, by the way, what a grand thing it is to *have* a sister! Of course, you all know I think a wife is about the nicest thing in the world; but if one hasn't a wife, a sister is the next best thing. Dear reader, have you looked after that sister of yours as you ought? Do you realize what a gift, straight from the great God above, she is or ought to be? Suppose you go and tell her now what I am saying; and you may add, too, that I have had large experience, and am good *authority* in the matter.

The St. Johns River is one of the prettiest rivers in the world. Oh! I forgot to mention

*I hope our readers will excuse me for once more touching on Electropoise right here. These people have the cheek and effrontery to claim that they too have "evolved and studied up" some great invention and discovery, whereas they have been only hatching up a series of lies. So ingeniously have they built up their cause that one might well be deluded if he did not look closely into the matter.

that there is a host of *little* rivers, or sort of side issues, perhaps you might call them, that branch off from the St. Johns, and they turn and twist in every direction. The water in these little rivers is like that mentioned in Georgia. It has a brilliant dark color, from the roots of the tropical vegetation probably; and when the water is still it reflects the luxuriant growth upon its banks like a polished steel mirror. When we first came down to the St. Johns River I was agreeably surprised to find my old friend, the water-hyacinth, all along the banks, and lining the edges of the stream and its tributaries for *miles and miles*. Some places they grow out into the river for several rods. Here is a fact for our experiment stations. Friend Brown tells us that, six years ago, there wasn't a water-hyacinth on the whole river; but some one threw in a plant. Now there are acres and acres of it, and great clumps looking like little islands are constantly floating down. When we landed for dinner I discovered these plants sailing up stream—or, at least, so it seemed to me. I asked for an explanation, and was told the water of this river runs *both ways*—up stream when the tide is coming in, and down stream when it is going out. The women-folks of our party pitched into me because I remarked, "Friends, I have often heard of contrary women; but I have never before seen a *river* that changed its course, and went directly contrary in just one short twenty-four hours." The raftsmen, whom we found along the river, take advantage of this queer phenomenon for transporting their logs. They let their rafts loose when the current is in the direction they wish to go.

Somebody said there wasn't any good drinking-water in Florida; but after drinking several times the water I dipped from the side of the boat from the St. Johns River and tributaries, I call it excellent—in fact, as nice as rain water caught from the clouds, in a clean tin pan.

The dark color, which I mentioned before, Mr. Brown says is caused by tannic acid from the roots of various trees along the shore; but this in no way affects the taste, so far as I can discover. The St. Johns River in some places is more than five miles wide, and I should be quite happy indeed if I could always have as good water as this to drink when I am thirsty.

A FISH-STORY.

Of course, our picnic party fished on the way. Well, I am not going to tell just how many fish we caught; but friend Brown says there is a place on the Indian River where, if you go out in a boat and carry along some lights, the fish will jump into the boat in order to get to the light; and if you don't put out the lights when the boat is full they will actually jump in until the boat sinks. We have not been to that place yet; but as Mr. Brown is a very good man, we feel quite sure it must be true. Friend Blackmer was wicked enough to say that it seemed to him it was *considerable* of a "fish-story." I did see a fish with my own eyes that I thought must be an alligator, and a big one (a yard long or more, I mean); but the rest of the party assured me that it was a black bass, my favorite dish.

When we arrived at Daytona I thought very likely my wheel might be the only one in town; but as we prepared to get off the train I was agreeably surprised. Wheels for both ladies and gentlemen were everywhere, and I soon found out the secret of it—the beautiful shell roads and cement streets and sidewalks, besides the splendid wheeling either up or down along the beach. Many of our older readers are more or less acquainted with Dr. Jesse Oren, who lives in Laporte City, Ia., in summer, and Daytona in the winter. Dr. Oren met

us at the train, and Constance and his daughter were soon old friends, to all appearance. Before we reached their beautiful home we were both quite captivated by the beauty of this place. Most of the inhabitants are well-to-do people from the North. The consequence is, the dwellings are all fine ones. The people are intelligent, and up to a high state of civilization. The beautiful roads are made from crushed oyster-shells, and these are obtained along the beach and near the river, heaped up in great mounds in many places, evidently left by a former race of people who piled up the shells after having used the contents for food. Among the shells are found fragments of pottery, which from their similarity have marked these places as the work of the mound-builders, found so generally over the United States.

Another way of paving the streets is from a kind of cement or marl, spoken of heretofore. This cement is found in various places, a mile or two out of town, occupying a foot or two just below the surface of the forests. The forest-trees are removed, the black woods dirt carted to town for gardens and lawns, and then the marl is taken out in huge blocks, pulverized, mixed with water and sand, then poured down for pavements.

Here for the first time we see forests literally made up of palms and palmettoes. The sight of these beautiful straight trunks or smooth stems running away up fifty or sixty feet without a branch or limb, and then ending with a tuft on top, again and again makes me feel strangely, some way, as if I were in fairyland. Just imagine a dense forest made up of nothing but these trees, ranging from a palmetto just coming out of the ground, all the way up to a full-sized tree.

If you are out in the woods, and get hungry, and are so fortunate as to have an ax, you can chop out a good chunk of cabbage from any cabbage-palmetto at any season of the year, and you may eat your cabbage cooked or raw. The doctor says you would hardly know it from common cabbage, but you will have a lot of work to get it out. These beautiful trees are left all through the streets, dooryards, gardens, and back yards all over Daytona. The main street is 100 feet wide, left this width to preserve the beautiful native forests of palmettoes and live-oaks, draped with the moss I have described.

The adjoining pictures give you a glimpse of what we see about this beautiful place, the one showing the blossoms in the head of a cabbage palmetto; and great quantities of beautiful honey are gathered every year from this source. Dr. Oren has been spending his winters here for the last ten years. He is now engaged in putting up some beautiful cottages for rent to bee-keepers or others who may wish to stay over winter here. A pretty little cottage that he says was built at a cost of \$500 has so much captivated my fancy that he has promised to have a picture of it taken to be given to the readers of GLEANINGS, at an early date. Such a cottage rents for \$90 a season, the season to be a whole year or any part of the year, only you must pay the \$90 if you have it during the season that Northerners usually come here. Bee-keepers will certainly do well to take in Daytona, and they shouldn't fail to call on Dr. Oren, for he can post them in regard to almost every thing they want to know. We find here these same artesian wells that are such a providence to all of Florida. By putting down a pipe only about 80 ft., enough water pours out for family use; and by going down still farther a much larger volume of water is obtained. Dr. Oren has just one such well for a group of cottages, and it furnishes something

The New Craig Seedling Potato.

For full description of this Potato, see page 959 of this journal for Dec. 15, 1894. Prices: 1 lb. by mail, postpaid, 25 cts.; ¼ peck, by freight or express, \$1.00; peck, \$1.75; ½ bushel, \$3.00; bushel, \$5.00; barrel of 11 pecks, \$12.50. The above prices will hold good as long as our stock lasts. All orders by mail will be filled as soon as received. Orders by express will be shipped at once unless ordered otherwise. All orders for potatoes by freight will be filled April 1, or soon after that time, unless directions are given to ship at an earlier date. In this latter case I do not assume responsibility for loss in freezing; but where it is desirable to ship earlier, and customers have bad luck, I expect to help them out so far as I can consistently. In regard to my responsibility I would refer you to A. I. Root. In fact, where it is more convenient you can order potatoes of the A. I. Root Co., instead of sending your orders to me.

GEO. E. CRAIG, Zimmer, Franklin Co., O.

B 4 U Buy Seeds or Plants,

Send for my Annual Catalog. It is neatly gotten up; no old stereotyped matter about it; nothing sensational. The Best Varieties truthfully described and honestly priced. A. I. Root says, "I believe I have read every catalog you have put out clear through, and I wish all seedsmen would tell us their experience with different varieties as frankly as you do." True Prizetaker onion seed and plants a specialty. Vegetable and small-fruit plants of all kinds, trees, and supplies for gardeners. Send for free catalog at once, or send 10c for catalog, a pkt. of a new smooth very early tomato, a pkt. of the best new lettuce, a pkt. of true Prizetaker onion, and a pkt. of choice flower seeds, all for 10 cents.

Christian Weckesser, Niagara Falls, N. Y.

METAL WHEELS for your WAGONS.

Any size you want, 20 to 56 in high. Tires 1 to 8 in wide—hubs to fit any axle. Saves Cost many times in a season to have set of low wheels to fit your wagon for hauling grain, fodder, manure, hogs, &c. No resetting of tires. Catlg free. Address
EMPIRE MFG. CO.,
Quincy, Ill.

SWEET-CLOVER SEED.

If any of our readers have sweet melilot or Bokhara clover seed to sell, we shall be glad to have them mail us samples, stating how much you have and what you ask for it per lb. We are sold out, and orders are coming quite freely.

LOCAL DEALERS IN BEE-KEEPERS' SUPPLIES.

As we go to press we are just issuing our circular of prices to local dealers. We desire a progressive agent to represent us in every good locality for bees, and we have special inducements to offer. If your name is not already on our books as an agent, and you are acting in that capacity, let us hear from you.

ALSIKE CLOVER SEED.

The supply of alsike seed seems to be plentiful, and our offers for it have been so freely accepted that we now have a good stock of choice seed which we are able to offer at lower prices. For the present we offer choice seed at the same price as peavine or mammoth clover—16c per lb.; \$2.00 per peck; \$3.80 per ¼ bush.; \$7.20 per bush.; \$14.00 for 2 bush., bag included in each case.

BEESWAX ADVANCED.

The market continues bare of beeswax, and prices are higher. We quote an advance of 2 cents a pound over our last quotations, and will, until further notice, pay 28c cash, 31c in trade, for average wax delivered. We can not offer refined wax for sale in small lots for less than 35 cents. Is there not an opening at such prices for bee-keepers in some sections to produce wax rather than honey, at the present low prices for the latter?

SIMPLICITY AND OLD-STYLE HIVES.

Our readers who have received new catalogs, have no doubt noticed that we do not list the Simplicity portico and old-style chaff hives. We consider the Dovetailed hives superior, and they are lower in price. If any old customers who have a supply of these old-style hives, and do not care to change, wish to buy more of the same kind, remember we are still prepared to furnish them at the same prices as heretofore.

DOVETAILED HIVES—NEW LIST.

If any of our old customers do not like the new plan we have adopted this year, of including nails and brood-frame starters with complete hives, they are at liberty to order hives at the old list, put up in the old way. In that case be careful to state in your order that you order from old list. The freight rebate mentioned inside of front cover of catalog will not apply to such orders, but only to those ordered from the new list which comply with the conditions made in the catalog.

COMMON-SENSE BINDERS.

M. H. Mendleson, of Ventura, Cal., recently asked the price of these binders in lots of 6 to 12, and adds, after acknowledging receipt of a sample, "It is so convenient and neat, I'd like to bind GLEANINGS for a number of years past." This only shows how the binder is appreciated. May be there are other

readers who would like to do likewise. Price of the binders, all cloth, 65c each; with leather back and corners, 75c; postage, 17c extra. In lots of 3 or over, 5c each less; 10 or more at 10c each less. There is no better or more convenient binder made.

KIND WORDS FROM OUR CUSTOMERS.

QUEENS SUCCESSFULLY MAILED TO TASMANIA.

It is with pleasure that I have to inform you that your select tested queen, dispatched to me in September, arrived all safe and in fine condition on the 16th of October. There were only two dead bees in the cage. I introduced the queen by hanging the cage in the hive for 24 hours, and then turned her loose, and she is laying quite vigorously.

Cedar Hill, N. S. W., Nov. 1, 1894. A. E. AYERST.

Mr. Root:—The two beautiful queens you sent me arrived here on the evening of the 19th of October. They were quite frisky, and only four dead bees in each cage. Probably they were hurt in caging them. They were so fresh and lively that I feel quite sure I could have added a little more candy and sent them off for another 14 or 21 days' journey.

W. P. CLENNETT.

Port Esperance, Tasmania, Nov. 1, 1894.

Mr. Root:—For about fourteen years we have kept company. These years have had their joys as well as their sorrows. Your kind talks have helped to clear away many dark clouds, and left the skies brighter. GLEANINGS makes me feel as if the world, after all, consisted of something besides dollars and cents. May the blessing of God go with you to the end.

J. E. LAY.

Hallettsville, Texas, Dec. 24.

OUR AGRICULTURAL BOOKS, ETC.

We do not agree out here with W. I. Chamberlain with regard to 2 ft. 6 in. being sufficient in heavy clays. The book is full of useful practical wrinkles, especially that with regard to the method of cutting the clay in digging by hand. I see no reference to it in the Tile Drainage; but the deeper the pipes are laid, the smaller they may be. Here, for instance where we have an average rainfall of 49 inches per annum, and occasionally 12 or 13 inches in two days, if we drained 2 ft. 6 in. only, and used 1 inch tiles, it may be the soil would become water logged, and tiles unable to carry it away; but where they are 4 ft. down, the soil acts as a regulator, and gradually passes it through; whereas in shallower drainage the water passes through with more of a rush. Of course, with deep drainage the soil is much more drought-resisting than with shallow, and you do not seem to be free from that complaint, "want of water," yet. The book entitled "Our Farming" is just grand, and reads like a tale. The chapters on clover and manure-saving are worth many times the price of the work. We are having a splendid season here this year, and the bees are booming. Honey is cheap—about 5 or 6 cents per lb. for extracted, wholesale; but some of our apiarists get large yields. My district is very poor and limited.

Largest Factory in the West. **COMPLETE STOCK.**
GOOD SUPPLIES and LOW PRICES. Our Motto
 We are here to serve you, and will if you give us a chance. **Catalogue Free.** Address
 1-6cl **LEAHY MANUFACTURING CO., Higginsville, Mo.**

Blue Beauty or Giant Perennial Sweet Pea.—Flowers two inches across and two and a half inches long; a lovely shade of azure-blue with feathery markings of deeper blue and a dash of pure, clear white in the centre of each. Forms a dense vine 6 to 8 feet high, covered with blossoms, surpassing in beauty the finest Clematis. Hardy, growing more beautiful from year to year. Seeds, 15c per packet.

Pink Beauty, (Kosteletzkyia).—One of the greatest floral novelties of the age. Perfectly hardy and covered all summer and autumn with flowers as large and almost as round as silver dollars, which are of the most tender and charming bright rosy-pink imaginable. Blooms first year from seed and forms a dense plant three feet high, that remains in perfection a lifetime. Succeeds everywhere. Seeds, 25c per packet.

Strong blooming Plants, of either, by mail, each 25c., or 3 for 50c.

ELEANOR, the only large very early Strawberry. **MARY and HENRY WARD BEECHER**, the biggest and best of all strawberries. **PLYMOUTH ROCK**, the most valuable cherry. **LOVETT'S BEST BLACKBERRY**. **SUNBEAMS CANNA**, immense pure golden flowers. **FAXON SQUASH**, the finest vegetable of modern times. A host of other valuable novelties, and all the good old sorts of **FRUITS, FLOWERS and VEGETABLES**.

A FLOWER GARDEN for 25c.

To prove by results the superior quality of our seeds we will mail ten full-sized packets of Flower Seeds for 25 cents. These packets contain hundreds of varieties and with the simple culture a child of ten years can give, will produce a brilliant display of beautiful flowers all summer and autumn and plenty for cutting for the house. Also ten full-sized packets of Vegetable Seeds, all choice varieties, selected especially for boys, for 25 cents.

Everything is fully described in our **Guide to Horticulture**, a book of 150 pages, copiously illustrated and beautifully printed; and full instructions given for planting, pruning, culture and management. To all who order any of the above, the **GUIDE** is sent **FREE**. To those who send **TEN CENTS**, and say where they saw this advertisement, we mail a bulb of the lovely Variegated-leaved Tuberose, three bulbs of Gladiolus and the **GUIDE**.

The LOVETT CO., Little Silver, New Jersey.

HONEY COLUMN

CITY MARKETS.

KANSAS CITY.—*Honey.*—The stock of comb honey is large; market well supplied. Fancy white 1-lb. combs, 15; amber, 12@13. Receipts of extracted, light; white, 7; amber, 5½@6; southern, 4½@5. Beeswax, 22. **HAMBLIN & BEARSS,**
Feb. 20. Kansas City, Mo.

BOSTON.—*Honey.*—We beg to quote you our market without change to price, and with a little better demand for honey. Fair stock on hand. hand, with some inquiry. **E. E. BLAKE & CO.,**
Feb. 8. Boston, Mass.

SAN FRANCISCO.—*Honey.*—Honey is scarce, but not in active demand. We quote extracted honey, 6@7; comb, 1-lb. frame, 8@10. Beeswax scarce at 27@28. **SCHACHT, LEMCKE & STEINER,**
Feb. 13. San Francisco, Cal.

KANSAS CITY.—*Honey.*—There is no change in the market on honey or beeswax. Honey is very slow sale. Business otherwise is about the same. **C. C. CLEMONS & CO.,**
Feb. 14. Kansas City, Mo.

DENVER.—*Honey.*—Our market remains without much change. No. 1 comb honey in 1-lb. sections moves slowly at 11@12; No. 2, 9@10. Extracted, No. 1, in 60-lb. cans (2 in a box), 6@7. There is an improvement in the demand for extracted honey. We can handle to advantage a quantity of pure beeswax at 22@25. **R. K. & J. C. FRISBEE,**
Feb. 11. Denver, Col.

ST. LOUIS.—*Honey.*—Inquiries are larger, and demand somewhat better. We quote choice clear comb, 14½@15; amber, 13@13½; extracted, in barrels, 4@5. Prime yellow beeswax, 25½. **D. G. TUTT GROCER CO.,**
Feb. 19. St. Louis, Mo.

PHILADELPHIA.—*Honey.*—Comb honey slow sale. Large lots offered at 9@11. No pure white-clover in this market. Extracted honey is not in such good demand, on account of storm paralyzing all business; fair sale at 4@6. Beeswax very scarce; sells quickly at 30@32. **WM. A. SELSER,**
Feb. 19. 10 Vine St., Philadelphia, Pa.

NEW YORK.—*Honey.*—We are gradually working down our stock of comb honey, and the indications are that we shall succeed in disposing of all of the white honey, and possibly all of the dark, during the spring, at following quotations: Fancy white 1-lbs., 12; fair, 10; buckwheat, 8@9. The market is well supplied with extracted. Demand is fair for choice grades, while common stock is neglected. We quote: White-clover and basswood, 5½@6; buckwheat, 5@5½; Southern, 45@55 per gallon, according to quality. Beeswax firm, and in good demand at 30@31. **HILDRETH BROS. & SEGELEN,**
Feb. 20. 28 & 30 Broadway, New York.

MILWAUKEE.—*Honey.*—The market does not seem to present any new features on honey since our last report. The demand has been dragging, and we suppose the very cold weather has had some influence on consumers. Yet we think it would be good for them to eat more instead of less. We quote 1-lb. sections, best, 15@17; average, 13@15; common, 12@14. Extracted, in barrels, white, 6@7; same, in kegs, 6½@7½; dark, in barrels and kegs, 4½@6. Beeswax, 24@26. **A. V. BISHOP & CO.,**
Feb. 21. Milwaukee, Wis.

CINCINNATI.—*Honey.*—Demand is quiet for all kinds of honey. Best white comb sells at 14@16 in the jobbing way. Extracted brings 4@5 on arrival. Beeswax is scarce, and in good demand at 23@28 for good to choice yellow. **CHAS. F. MUTH & SON,**
Feb. 20. Cincinnati, O.

BUFFALO.—*Honey.*—The honey market is very quiet; still it is moving off in a moderate way. Fancy, 13@14; choice, 11@12; poorer grades are very dull, and at irregular prices. Buckwheat honey slow at 8@10. Extracted, very little in market, and very little demand. **BATTERSON & CO.,**
Feb. 19. Buffalo, N. Y.

CLEVELAND.—*Honey.*—The demand for white comb honey is somewhat slow. No. 1 1-lb. sections are selling at 13@14; No. 2, 11@12. No. 1 water-white extracted, 6@8. Beeswax, 28@30. **WILLIAMS BROS.,**
Feb. 18. 80 & 82 Broadway, Cleveland, O.

DETROIT.—*Honey.*—Stock of comb honey slowly decreasing. Best white continues to sell at 14@15. other grades, 11@13. Extracted dull at 6@7. Beeswax in good demand at 27@28. **M. H. HUNT,**
Feb. 19. Bell Branch, Mich.

CHICAGO.—*Honey.*—Since the weather has moderated, a better demand has been felt on the market; yet the sales are of small volume. White comb brings 14@15, according to its grade; dark is slow at 8@10. The demand for extracted is not brisk, and stocks are fair, of all kinds except white-clover. It sells at 5½@7. Beeswax, 28c for ordinary run. **R. A. BURNETT & CO.,**
Feb. 21. 163 So. Water St., Chicago, Ill.

FOR SALE.—Three tons of pure basswood honey in 30-gallon barrels; also nearly three tons in 15-gallon kegs. Price, 6½c; in lots of a ton or more, 6c, f. o. b. Barrels at Mauston, kegs at Durand, Wis. Address: **F. McNAY,** Mauston, Wis.

Closing out balance of my fine extracted basswood honey at 7c f. o. b. Who is not supplied?
ELIAS FOX, Hillsboro, Wis.

ALFALFA HONEY, very white, thick, and rich. Two 60-lb. cans at 7c. Same, partly from cleome (tinted), 6c. Samples, 8c. **OLIVER FOSTER,** Las Animas, Col.

We yet have extracted alfalfa at \$7.80 per box of 120 lbs. **AIKIN BROS.,** Loveland, Colo.

BEESSWAX WANTED.—Will pay 31½c cash for absolutely pure beeswax that will stand chemical test. Write me at once. **WM. A. SELSER,** 10 Vine St., Philadelphia, Pa.

BUFFALO, N. Y. Unsurpassed Honey Market.

CONVENTION NOTICES.

The Utah Bee-keepers' Association will hold its semi-annual meeting on Thursday, April 4, at 10 A.M., in the Fish Commissioner's rooms, in the new city and county building, Salt Lake City.
GEO. E. DUDLEY, Sec., Provo, Utah.

The next meeting of the Western Washington Bee-keepers' Association will be held on Monday, April 8th, in Horticultural Rooms, City Hall. Bee-keepers are invited.
G. D. LITTOY, Sec., Tacoma, Wash.

Peaches.

CROSBY FROST-PROOF.

—If you want Peaches every year, and plenty of them, plant the Crosby. It fruits in New England every year, never having failed in eleven years, even when all others were killed by the winter. It is of large size, beautiful orange yellow, splashed with carmine, and of best quality, ripening about mid-season. 20 cents each; \$2.00 per dozen, postpaid.

CHAIR'S CHOICE.—A very large, late, yellow-fleshed variety, very handsome; rich, juicy, firm; flesh of excellent quality; freestone, and a superior canning-peach. 20c each; \$2.00 per dozen, postpaid.

LOVETT'S WHITE.—For a late white Peach, nothing could be more desirable. Large, perfectly white, freestone; an annual bearer of rich, luscious, juicy fruit. 20 cts. each; \$2.00 per dozen, postpaid.

MOUNTAIN ROSE.—An old reliable and very valuable Peach, ripening early; large size, skin whitish, and nearly covered with rich, dark red; a valuable family and market sort. 20 cents each; \$2.00 per dozen, postpaid.

Larger trees of above, by express, at same price. I can also furnish Crawford's Early, Crawford's Late Elberta, Beer's Smock, Stump, Old Mixon, Wonderful, Ford's Late White Peaches. 20c each; 6 for \$1.00, postpaid; or larger, by express, at purchaser's expense, at same price.

The above "ad." is copied verbatim from a beautifully illustrated catalog for 1895. These descriptions are accurate. The peaches are just as represented. I would, however, select Ford's Late and the old Smock as worthy of being emphasized—equal to any peaches ever grown. I have all the sorts named above, and more. All are guaranteed true to name. Great pains and care will be taken that every tree that I send you shall grow. 10 trees, one or several sorts, by mail, 60c; 100 trees, by express or freight, \$4.00.

Japan Plums. Abundance, Burbank, and Satsuma. By mail, 5 for 60c; by freight or express, \$10.00 per 100.

Flora Vista, San Juan Co., New Mexico, }
Jan. 17, 1895. }

John Cadwallader.—Dear Sir:— * * * I received the order of 100 peach-trees last spring. They reached me in splendid condition. Also ten plums.
HENRY STEINBACH.

Cedar Grove Farm.

John Cadwallader, Proprietor, North Madison, Ind.

References: } First National Bank, Madison, Ind.

Please mention this paper

For Sale, at hard-times prices, a winter home at Tampa, Fla. Lot and two cottages. Rent of one cottage pays good interest on investment. Twenty best colonies of bees in apiary, ordered before April to ship May 1, \$70.00. Write for particulars. Mrs. F. Averill, Howardsville, Va.

For Persons

Reference, Editor
of Gleanings.

Desiring a milder climate, now is the time to invest in Florida. For information, write F. Danzenbaker, Box 100, Jacksonville, Fla.

For Sale. \$450 buys my home and apiary, just inside city limits; 1 acre of land, 4-room house, good shade and fruit trees, 25 colonies of fine Italians; lots of sweet clover all around me. Address P. J. T., Box 2, Fredonia, Wilson Co., Kan.

Wants or Exchange Department.

Notices will be inserted under this head at one-half our usual rates. All advertisements intended for this department must not exceed five lines, and you must say you want your advt in this department, or we will not be responsible for errors. You can have the notice as many lines as you please, but all over five lines will cost you according to our regular rates. This department is intended only for bona fide exchanges. Exchanges for cash or for price lists, or notices of offering articles for sale, can not be inserted under this head. For such our regular rates of 20 cts. a line will be charged, and they will be put with the regular advertisements. We can not be responsible for dissatisfaction arising from these "swaps."

A GENTLEMAN owning a fruit-farm near this city wishes to employ a man with experience in the bee business to build up an apiary and meanwhile assist on fruit-farm. Address
WALTER S. POWDER, Indianapolis, Ind.

I told you so.

Mrs. Atchley:—The one-frame nucleus I got of you last spring gave me 120 well-filled one-pound sections.

J. A. SMITH, Heber, Utah, Oct. 9, 1894.

Now, haven't I told you that it will pay to send bees north in the spring?

One-frame nucleus, \$1.00; 10 or more, 90c each. Bees by pound, same price. Untested queens to go with them, 75c each.

Untested queens by mail, \$1.00 each; \$5.00 for 6; \$9.00 per dozen, till June; after, 75c each; \$4.25 for 6, or \$8.00 per dozen. I breed the leather-colored Italians, 5 bands, and Carniolans, in separate yards, at safe distance.

Tested, 3 bands, \$1.50 each; 5 bands or Carniolans, \$2.50 each.

Fine breeders of either race, or imported queens, \$5.00 each. Full colonies with untested queens, \$6.00.

Ask for discounts to dealers, and by quantities.

The only steam bee-hive factory in south Texas. Root's goods, Dadant's foundation, and Bingham smokers.

Safe arrival on every thing guaranteed. Send for FREE catalog that tells all about raising queens.

JENNIE ATCHLEY, Beeville, Bee Co., Texas.

Woodcliff Business Queens.

To please all, am breeding both Leather-colored and Golden 5-banded Italians. Have five apiaries, 3 to 5 miles apart, running 350 nuclei. Your orders filled promptly. Can furnish queens from March 1st to Nov. 10. The Leather-colored 3-banded Breeder, imported from Italy, Oct., '94.

The Golden 5-banded Breeder, selected from 1000 queens, some producing 400 lbs. of honey to colony. State what you want, and send orders now for early delivery. Guaranteed queens, 75c; special low price in quantities. Send for descriptive catalog.

Wm. A. Selser,
Wyncote, Pa.

World's Fair Medal

Awarded my Foundation. Send for free samples. Dealers, write for wholesale prices. Root's new Polished Sections and other goods at his prices. Free Illustrated Price List of every thing needed in the apiary.

G. B. LEWIS CO.,
Watertown, Wis.

420 Lbs. Average

Is what my bees gave that I moved to the man-grove; those at home, 300 lbs. each; 5-banded bees, too. Queens, bred for business from this stock, will be sent in 1895 for \$1.00 each until May; per doz., \$8.00. Circular free.

J. B. CASE, Port Orange, Fla.

Vol. XXIII.

MAR. 1, 1895.

No. 5.

STRAY STRAWS

FROM DR. C. C. MILLER.

"No ONE can write for bee-keepers but bee-keepers," says *British Bee Journal*.

DADANT says queens are less likely to go up and lay in shallow frames than in deep ones.—*A. B. J.*

"APICULTURAL literature was never better than it is to-day."—*Review*. Right you are, W. Z.

336 POUNDS of comb honey is what J. D. Endicott reports in *A. B. J.* from a colony hived June 10.

TWO COLONIES whose hives stood 3 inches apart, are reported in *A. B. J.* as working together all summer.

FORMALIN, a near relative of formic acid, is spoken of in the German bee-papers as the coming cure for foul brood.

GRAVENHORST thinks bees contract their entrances toward winter, not to keep out enemies, but to keep out chilly winds and the light.

IT IS AN OLD fable, that, to eat fish, makes brain. U—m! Why is it that fish are so plentiful and brains so scarce?—*Dr. Peiro, in A. B. J.*

PEACH-PITS, one eaten every hour or so, are recommended by Dr. Peiro, in *A. B. J.*, for cough and whooping-cough; and for dyspepsia, baked apples.

GRAVENHORST finds that a swarm furnished with foundation from the start is not a whit ahead of one which is first compelled to build five or six natural combs.

A COMB, no matter how many times it has been filled and emptied, becomes constantly better and stronger for extracting purposes.—*Chas. Dadant, in A. B. J.*

A MUTUAL-INSURANCE company of bee-keepers at Lueneburg is mentioned in *Centrablatt*, having had a successful career of 15 years. It prevents damages to bees through spite work,

as the loss to the individual bee-keeper is slight.

J. A. GREEN says, in *A. B. J.*, that he once had a large lot of queen-cells built in January, and sold the royal jelly at \$25 an ounce, presumably for medicine.

H. W. BRICE says in *B. B. J.*, that, when he has trouble uniting bees, it's always those with old queens, while bees with young prolific queens may be united almost any way.

GREAT WILLOW HERB, *Epilobium angustifolium*, says R. H. Ballinger, in *A. B. J.*, has for years been used by the Indians from Neah Bay to Alaska for making thread and fish-nets.

THE *Nebraska Bee-keeper* gives quite a full list of honey-plants in Nebraska, and says, "It well repays the apiarist for even breaking off small limbs" of box elder so the bees can get the exuding sap.

QUICK CURE for bad cold. Mix a tablespoonful of honey in as much lemon juice in a big pint of water, dusting into this a little cayenne pepper. Drink at once, and keep warm in bed.—*Dr. Peiro, in A. B. J.*

IN BRUSHING bees off combs when it's too cold for them to crawl back into the hive, put two or three bottomless hive-bodies over the hive and brush the bees into this as into a funnel. So says J. A. Green, in *A. B. J.*

MOTHER.—"You are at the foot of the spelling-class again, are you?"

BOY.—"Yes'm."

"How did that happen?"

"I got too many z's in scissors."—*Good News*.

A PARADISE for bees is described in *A. B. J.*; and then the question is asked, "How many bees can be kept there in one apiary?" The answers vary from 75 to 500 colonies, which goes to show that no one knows much about it.

THE *Review* reports a new non-swarmer arrangement of L. A. Aspinwall. Near swarming time, between each two brood-combs is put a half-inch board filled with holes like cells, but running clear through. The bees can't fill

those holes, and they think there are too many empty cells to swarm.

"BEES WILL WINTER better in the cellar, if in chaff hives, than they will in single-walled hives, providing they are fixed as they should be in the cellar." Each hive is raised three or four inches from the bottom-board, and its cap is taken off. The bees eat less, and hence are healthier. So says Doolittle.

NEAR THE CLOSE of the main honey-flow, put ripe queen-cells in supers or extracting-stories, and in four cases out of five your old queen will be superseded.—*E. F. Quigley, in Review.* I tried a lot in that way, and all failed. But I did it at the beginning of the honey-flow.

"DO THE FIVE-BANDED Italians average better than the three-banded or worse?" To this question in *A. B. J.*, Doolittle replies, "Equally good or better during 1894." Dr. Tinker thinks favorably of them, while the rest either think there is no difference, or that they are not so good.

THIS JOKE is on me: T. P. Andrews sends a postal: "Why don't you look in the Standard dictionary when you want to know what a word like *lysol* means?" Looking, I find, "Lysol. A saponified product of coal-tar, containing cresol: used as a disinfectant." So that's the new foul-brood cure. But, say; isn't there a law against writing "sassy" things on a postal?

DADANT, in the *Review*, takes the ground that the greater or less ductility of foundation is not due to the manner in which it is *melted*, but to the *manipulation* that it undergoes when cold; that rolled foundation is like wrought iron, and Given or cast foundation is like cast iron; and, moreover, that, "foundation which has been standing a long time becomes more and more brittle, so that, at the end of a couple of years, a piece of molded foundation is about as brittle as a piece of fresh Given foundation." [We are now working on a set of *rolls* to make Given foundation. In comparing the article from the press, I found that its distinctive feature was thick and heavy side walls, and these can be made on rolls as well as on the press. Our Mr. Washburn, from a sample of Given, made a punch to emboss the rolls that I expect will duplicate the side walls of Given foundation made by Mr. Taylor on his press. We made some experiments in this line last summer, and the results were exceedingly gratifying. This time we propose to go one step further, and make an exact duplicate of Given on *rolls*. Now, then, we confidently expect that this wax will have all the good qualities of both the rolled and the Given foundation. Well, now, do not go and send in orders; because, as soon as the wax is ready, due announcement will be made, so that all can test it who desire.—*Ed.*]

LARGE HIVES.

WHY THEY ARE MORE PROFITABLE; EGG-LAYING CAPACITY OF QUEENS, AND ITS RELATION TO THE SIZE OF THE BROOD-NEST.

By C. Dadant & Son.

Friend Root:—Your little editorial on large hives, page 101, was duly perused; and the taunt that it contained, viz., "Now that there are more bee-keepers on their side, perhaps they can set forth their views with more assurance," had the desired effect; for we were preparing an article in reply when we received your letter calling our attention to this matter. Indeed, after all we said on the subject, in *Langstroth Revised*, especially pages 150 to 153 (see note at bottom of page 152), and after all the articles we have written from time to time in different bee-journals, what do you expect us to do to get the bee-keepers to try large hives? Must we adopt the plan of the train-robbers, who ask for your money or your life, and demand of you and others "*large hives or your life*"? Would that be setting forth our views with "assurance enough" to suit you?

We have never lost an opportunity of setting forth our preference for the large hive and for the large frame; nor is it a whimsical fancy that led us to this preference, but a protracted experience with three kinds of hives—the ten-frame Langstroth, the eleven-frame Quinby, and the fourteen-frame American. We began with a nine-frame hive here, in 1864 or '65, the frames of which were about like the American frame, and increased these hives to 14 frames in the course of a few years. We have had for 30 years from 10, at the beginning, to 60 hives of this style in use. We still have about 60 of them. We then tried the eight-frame Quinby; and afterward, in 1868-'69, made these hives with from 10 to 14 frames, finally settling on the eleven-frame as the best size for us. Then, as we were selling bees in hives in large numbers, in 1872-'76, we concluded that we had best keep the then most popular hive, the ten-frame Langstroth, and we made 100 of them. These, with a few eight-frame Quinby hives, were kept first in a separate apiary, and later were divided in equal numbers with larger Quinby hives in two different apiaries. In spite of the meager returns of those small ten-frame Langstroth hives, we kept a number of them until three or four years ago, for the reason that, when a colony of bees was purchased of us, it was usually wanted in a Langstroth hive; the bee-keepers who bought such colonies having their apiaries already stocked with this style of frame. But as we found, again

and again, that the smallest crops came from the smallest hives, on the average, and that, whenever the crop was short, twenty-seven out of every thirty small hives had to be fed, while the large colonies had generally enough, we transferred all the bees out of these ten-frame Langstroth hives, and we now have a lot of these old hives piled behind our honey-house, waiting for a buyer. But they will probably soon make kindling-wood.

The same experiments have been made by large producers in this country and in several countries of Europe, with the same results. Some of these are related in Langstroth Revised.

That a large hive gives better results may be easily explained, and without rational contest, since it can not be denied that the amount of honey gathered by a colony is in proportion to the number of bees the hive contains. The writers of old books on bee culture, being unable to reckon correctly the number of eggs that a queen could lay, had guessed it very much too low. Now it is proven that most of the queens, in favorable circumstances, lay 3500 eggs in 24 hours, during spring. We have ascertained that some of our queens laid more than 4000 eggs; and a bee-keeper, Mr. P. Bois, of Jersey, a reliable man, reported in the *Revue Internationale*, that one of his queens laid as many as 5000 eggs in 24 hours. Is there any thing improbable about this? Authorities agree that the queen can lay her weight of eggs in 48 hours, consuming honey in proportion. We have often seen a queen, in an observing-hive, lay six eggs in a minute; this would make 3600 in ten hours, 4320 in 12 hours. Now, as it takes 21 days for an egg to become a bee, if we suppose a possible laying of 3500 eggs the queen needs a number of cells equal to 3500×21 , or 73,500 cells, in addition to the cells needed for the indispensable stores of food, honey, and pollen.

The Langstroth frame measures 142 square inches; and as every square inch contains 55 worker-cells, 27 or 28 on each side, one frame contains about 7800 cells; an eight-frame hive, therefore, has but 62,400 cells, and a ten-frame 78,000. Deducting from this number about 20,000 cells for stores and a little space ahead (for the queen surely can not fill every cell as soon as vacated), we have, to receive the daily laying of eggs, 42,400 cells in the eight-frame, and 58,000 in the ten-frame hive; and this, divided by 21 days, gives us a capacity of but 2000 and 2800 eggs per day. In short, an eight-frame hive can accommodate only a rather inferior queen. Will you need authority for this? We can give you some very near home.

We read in the A B C of Bee Culture (are you acquainted with the author?) under the heading, "Loss of Queen," "If we assume the number of eggs a queen can lay in a day to be 3000, by taking her away a single day we should, in

the course of events, be just that number of bees short right during a yield of honey." Then the lack of room in a ten-frame hive reduces the laying, according to this author, 200 eggs per day, or 4200 during the 21 days; and the famous eight-frame hive reduces the number of workers, in 21 days, just 21,000. Would not this make a fine little swarm? What qualities do you find in the eight-frame that will make up for this loss? Mind, we take the number of only 3000; but what is the loss if the queen is capable of laying 3500 eggs or more per day? As a matter of course, even with these ten-frame hives you will not know what she is capable of doing, and you will ignore your loss altogether. We acknowledge that the author of the work above cited must not have been very sure that the average queen could lay that many eggs, else why should he ever advise any one to change from a ten-frame to an eight-frame hive? And yet when he states the probability of her being able to lay that number, he places himself with only the most conservative authors—Dzierzon, Thos. W. Cowan, and others.

In 1857, Berlepsch counted the eggs laid by a queen in 24 hours, and this number was 3021. Numbers of writers agree that the minimum laying of a good queen, in the busy season, is 2000 eggs per day. With your eight-frame hive you compel them to the minimum rate.

About three or four years ago a bee-keeper wrote, in the German bee-journals, that queens were unable to lay more than 15 or 16 days in succession, and stopped very often for five or six days at a time. The Swiss bee-keepers, who nearly all use large hives, investigated this matter, and unanimously reported that they had been unable to find a trace of any such intermissions. The explanation was easy: The German hives are all small, and the queens fill them very quickly. Their cessation of laying is caused by their being short of room before the hatching of the first-laid eggs.

In very small hives, not only the queen but the bees are dissatisfied, and swarm frequently. Some bee-keepers, who wish to increase the number of their colonies, may like this; but the men who have enough colonies, and want honey, do not relish the swarming so well, for it compels them to watch their hives, and often to leave their occupation to harvest swarms that are often of little value. The increase by natural swarming is less desirable than that by artificial division; for in the latter case the bee-keeper can select his breeders. Natural swarming is, therefore, objectionable in several ways.

You will object here, that you can give room to your bees by piling two or even three hives on top of one another, thus giving the queen all the space needed, and *more*. Aye, "*and more*." In fact, you give them too much space this time, and often too early, when the weather is too cool, or too late, when the crop is very near

at hand. These double hives contain 124,800 cells, while our large hive contains 99,000, or 25,800 less. Many of the cells, unoccupied with brood, will be filled with honey that will have to be extracted from frames containing brood, in many cases. Very often the reduction of such a large hive leaves the colony with too little honey for winter; while with the large brood-chamber we may be sure that we always leave enough, and we dispense with the removal of honey from the brood-combs.

We have ascertained that spring honey makes better winter feed than the darker honey of fall, and we are enabled to leave enough of it in the brood-apartment, without any manipulation, for the winter supply. With shallow supers over a large brood-chamber, we rarely get brood in the upper story, and have no difficulty in removing the bees in using the bee-escape, for the queen is usually where she belongs—in the brood-chamber. The manipulations for extracting are, therefore, much simplified.

The bee-keepers who use small hives have to use the queen-excluder when working for comb honey, because the queen is short of room, and lays wherever she can find space, without regard to the color of the comb, in those beautiful basswood sections which afterward give only a second-grade honey. The queen-excluder increases the expense and the work for the bee-keeper, and the unpleasantness for the bees.

Your double-story eight-frame hive is an unwieldy affair, too large when first doubled, and too small when reduced by half; too high for its width, and with too little room over it for a big crop of honey, unless you tier it up to the skies. With the large brood-chambers, all in one story, our breeding-room is always ready; the amount of honey left over is in proportion to the size of the colony; the breeding is pushed along uninterruptedly during spring, and the surplus capacity is very large, owing to the width of the hive. The most prolific queens are easily ascertained, and may be used as reproducers. As the colonies are all more populous than with small hives, their capacity for storing honey is larger, and their wintering is better insured by their greater strength.

Now, friends, if we have placed the matter before you with too much "assurance," blame but yourselves for it. We did not seek the discussion, but are always ready to take our own part.

Hamilton, Ill.

[I certainly did not intend to throw out a taunt of any kind; but if what may be construed as such has been the means of calling out a valuable article that we otherwise should not have received, I am glad it went in.

Regarding the use of two eight-frames, one on top of the other, versus a ten or twelve frame all in one brood-nest, I must confess I am gradually coming to the opinion, from the testimony so far received, that 16 frames, or the double brood-nest, is too large; that the

twelve-frame* capacity seems to be a maximum. But I am not prepared yet to accept the statement that this size is the best, all things considered, for all bee-keepers, although I am inclined to think it is about right for the Dadants. If, then, we must have a large hive, the weight of testimony seems to be so far in favor of not more than twelve-frame capacity. Now regarding the egg-laying of queens:

On page 138 of our last issue, Mr. Doolittle seems to have almost anticipated an answer to Mr. Dadant's statements. Among other things he says: "With the large hive the bees are quite likely to get the start of the queen, and commence to store honey in the brood-combs before entering the sections at all, and in such a case the bees seem loth to go into the sections." During the poor years of late it has been hard to get even an eight-frame brood-nest so crowded as to force any surplus above. Again, he says: "It is well to remember that all queens are not equally prolific; and while 20 per cent of our queens would keep the brood-chamber of a ten-frame Langstroth hive properly supplied with brood to give the best results in section honey, the other 80 per cent would not be prolific enough to do so; and that, because a queen may lay 6000 eggs daily by using plenty of comb capacity and coaxing, it does not necessarily follow that it is to the best advantage of the apiarist to accommodate or even coax the queen to bring her fullest laying capacity to the front at any time." Further on, he thinks that the queen should be rather above the capacity of the brood-nest than otherwise. From all his past experience he believes that 2400 eggs would be a good maximum average. In the same number, Mr. Boardman thinks it is not so much the *large hive* as the laying capacity of the *queen* that regulates the size of the colony.

My own views are subject to revision, for I can not, in the beginning of things, strike the golden mean. I do not wish to appear to be fickle, and jumping from one thing to another; nor do I desire to stick to one idea year after year, right or wrong, and try to bolster it up by all sorts of arguments. I do not wish to be construed as being strictly an advocate for an eight-frame hive, nor for a ten-frame or twelve-frame. In our catalog for this year we have given our customers the option of any one of the three sizes. We give them, as fairly as possible, the advantages of each size, considering the matter of locality, so that each one may decide for himself. If one is a beginner, and does not know what he wants, we recommend the eight-frame size, because the majority of our customers have elected it in the past; and because, too, when we were making the ten-frame size only, the pressure got to be so great that we not only admitted the eight-frame size on an equal footing, but later on gave it the foremost position.—Ed.]

EXPLANATIONS AND ANSWERS.

MISCONCEPTIONS CORRECTED.

By C. A. Hatch.

One of the perils and disadvantages of writing for the press is in being misunderstood and misrepresented by those who hold opposite opinions. I suppose one of the chief reasons for this is the poverty of written language as compared with spoken. In the written, all the

* A twelve-frame Langstroth has about the same capacity as the Dadant hive.—Ed.]

expression of features, inflection, and gesture are all lost; and what would be very easily understood in the way the speaker intended when standing face to face, becomes a mystery when reduced to the dead level of cold type. He must be a master indeed who can express his opinions and ideas as well with the pen as with the voice.

While I think none have willfully misinterpreted my articles on the eight and ten frame question, many have ascribed ideas and opinions to me that I never held, and that have been furthest from my thoughts while penning the articles; so I shall have to lay the cause to one of two reasons—either my poverty of expression is so great that I have failed to say what I wanted to, or their discernment has been so keen that they have read between the lines things that were never there.

My time is so taken up at present that I can not hunt up each specific case, but must generalize somewhat.

DO I BELIEVE IN AND PRACTICE TIERING UP?

Most assuredly, I do; and yet some seem to think that I advocate only side storage and the "Long-Idea" hive, simply because I think bees will increase faster, and get stronger by the beginning of the honey harvest, if a hive is used large enough to keep the queen laying up to her capacity, without putting another hive over it. After the harvest commences, tier up as high as you like—one, two, or three supers, as the strength of the colony will require. I do not remember of ever having a colony require more than three full-sized hives on top, to give all the room needed, but have had any amount of them that require four hives, in all 34 frames, to accommodate them.

QUEEN GOING DOWN OR UP.

I have never had any trouble from the queen going down after putting another story on, *if the top hive is allowed to get full*; but this filling of the top hive with brood is *always* at the expense of emptying frames in the lower hive, for I never had a queen that would keep *both* hives full of eggs; and if she is crowded down for lack of room above, it is two or three days before she will go, and hence so much lost time at the most critical time, just before the harvest begins. Therefore I'd rather have a hive up to her fullest capacity, and have her doing her best at all times.

E. France asks if I would call a queen that could keep only eight frames full a "boomer." Yes, indeed, I would; but when I say "full," I mean full and *kept* so.

WHERE THE QUEEN SHOULD BE KEPT.

After the honey harvest has commenced, and all has been done to get your force ready for onslaught of field and forest, it is of but small concern of mine where the queen is, or that they have a queen at all. In practice, no attention is paid to that part of the hive—i. e.,

the lower story; the main thing is to keep plenty of empty combs *over* the brood-nest.

THAT BEE-TREE PROBLEM.

The facts as to the condition of the combs and colony living in the tree, as described by Mr. France, are, first, the cavity occupied by them was largest in the middle, and tapered toward each end, being six feet long by $2\frac{1}{2}$ feet in the middle, and all the brood at the lower part, and two feet or more below the entrance. I infer that all the top part of the hollow was filled with honey, although Mr. F. does not say so; but as he says a tubful was taken from the two trees, and only two dishpanfuls from the other, the last must have had a washtubful, less the aforesaid two panfuls; as, of course, there was not much room, if any, for brood except at the lower end of the hive, or just *below* the honey, where I should expect to find it. Now let me answer Mr. F. by asking him a few questions, like any other Yankee. 1. Was not this at the close of or after the honey harvest? and was not the queen crowded down by the honey stored in the combs above? or had not she arranged things for consumption rather than for production? Remember, it is *before* the harvest I have been talking about, not *after*, when instinct teaches the bees to arrange their brood-nest for winter convenience and accessibility of stores. 2. Were the conditions, aside from time of year, the same where there was a continuous comb from top to bottom, and two hives, one over the other, with two strips of wood, and a bee-space varying all the way from $\frac{3}{4}$ down to $\frac{1}{4}$ inch? I do not presume there is one really essential thing that my good friend France would disagree about under like conditions. Our fields vary somewhat, and so require different management to meet those conditions; and this question of management answers many seeming differences of opinions. But this is leading into another field, and I shall have to leave this question for some other, so I can tell how I get along without the disadvantage of lifting my ten-frame hives much, and yet get all their advantages.

Ithaca, Wis., Feb. 11.

[I suppose, friend Hatch, you have myself in mind, as well as Dr. Miller and others who have been on the other side of the fence. I for one had not intended to misconstrue you, but perhaps I did so. In any event, I do not think your position can be misunderstood as above given. In the second place, you have the satisfaction of knowing that you started this discussion, and have brought to your assistance more bee keepers who are ready to support your views, wholly or in part, than you or any of us were aware of.]

I am afraid that some of our readers will not be able to decide this question for themselves. For instance, they will read Mr. Boardman's and Mr. Doolittle's articles in the last issue, and then read your own and Mr. Dadant's article above. All four are men of sterling integrity, and bee-keepers of large experience and ability. Then how shall we get at the truth? Locality seems to me to offer the only

solution; and if we are to follow the advocates of one or the other, we must consider our own locality compared with theirs. Perhaps I ought to say that the Dadants have a much better and more prolonged fall flow of honey than those who advocate a smaller size of hives. With the latter it is not desirable to have a large force of bees after the honey-flow, to be consumers and practically nothing else.—Ed.]

TEN-FRAME HIVES, MORE HONEY AND FEWER SWARMS; EIGHT FRAMES, LESS HONEY AND MORE SWARMS.

My hives are all eight frames but one. I have endeavored to follow carefully in the footsteps of the majority, notwithstanding the fact that my one ten-frame hive did just as well as the eight, and never swarmed, and the fact that my neighbors with ten frames get more honey than I. In fact, for three or four years I have been looking for some big report from eight-frame in *GLEANINGS* and *Review*; but the big reports for some reason all seem to come from the ten-frame hive. I am sure that I have lost money and honey in runaway swarms from my small hives. I am confident that, with ten-frame hives and high shade, I shall have non-swarmed bees, and shall not have to be always anxious about a shortage of honey in the hives. No more small hives for me at present. NEWTON AMERMAN.

Rice Lake, Wis., Feb. 4.

[I thought this would be a good item to put right after the article above; for, indeed, it confirms the position of Mr. Hatch when he had to fight single-handed.—Ed.]

CHAFF VS. DEAD-AIR SPACE.

NOT AN EIGHT OR TEN FRAME HIVE, BUT A COMBINATION OF BOTH.

By C. W. Dayton.

In a back number of *GLEANINGS* I find the assertion that there will be more bees reared in an eight-frame hive because it is warmer. I believe the bees form what is known as an "inside hive." By this is meant that, around the margins of brood, the bees arrange themselves in such solid lines between the combs as to prevent a circulation of air from within or without the cluster, for the purpose of keeping a high temperature there while they allow the rest of the hive to arrange its own temperature; consequently, in cold weather the walls are often coated with frost; and in Southern California, where frosts seldom come, we find the walls and unoccupied combs dripping with moisture. From this it would seem that the ten-frame hive is actually warmer than the eight, as the cluster of bees and brood would be able to locate farther from the outside walls. Even if the cluster was warm enough and near enough to the walls to dispel the moisture or frost it would require warmth to do it, and such warmth would disappear in the operation, and

could not aid in brood-rearing, as where there is no frost to be dispelled.

In Iowa I wintered bees in a room which was constructed entirely within a cellar. There was a beam extending from the outdoor air to the inside room. As the cold increased, the frost began to creep down that beam, inch by inch, until it finally reached the inside room. Then when the weather became warmer the frost retreated up the beam. The farther the inside room was from the outside wall, the more secure from frost. The thermometer said so. Would not this inside room correspond to the inside hive of a colony of bees, and the outer wall represent the outside hive? But the inside hive, of which we speak, is of the same size, whether the outside hive be adapted to eight, ten, or twelve frames. The more frames in the outside hive, the longer beam would there be required between the outside and inside cellar walls. In the large hive there is a wall of wood and a wall of dead air. Will any contend that six inches of chaff packing is no better than two inches of the same material? But it is a mooted question which is warmer—chaff or the space filled with dead air. Where a colony fills the hive, as is likely to be the condition in the eight-frame size, there is the protection of the outer wall only, when, with a hive of greater width, a dead-air space occurs. The more dead air, the more protection. If the whole interior of the brood-chamber were to be kept warm, then the less dead-air space the better. Mr. Langstroth designed to have the winter stores deposited in the rear end of the brood-frames. At that early date it seems to have been known that the long frame was longer than necessary for the accommodation of the brood. It might not be so very bad to have the winter stores in one end of the frames were it not that, a little later on, we *must* have a share of the working force of bees lodged there instead of above in the supers of sections, where they should be. Eight long Langstroth frames have the capacity of sixty-four $4\frac{1}{4} \times 4\frac{1}{4}$ sections. Eight crosswise frames contain 48 sections—a difference of sixteen. These sixteen sections would fill 2% of the crosswise frames. Let the two-thirds of a frame go while we set one of the whole frames on each side of the original eight, and it results in a ten-frame hive with brood in eight combs instead of the old eight-frame hive with brood in only six, and that much exposed at the remote points of the brood-sphere. There might be a comb of pollen also. Since it is admitted that the two outside combs in any hive are not occupied with brood, there would be only four or five brood-combs in the eight-frame hive, while there were six or seven in the ten-frame hive, resulting in more early bees and a more populous hive later on, to send bees into the supers. It would be like a light-weight and a heavy-weight pugilist, both in the same ring; that is, the ten-frame colony

would be the largest—more bees in a larger hive, and a larger super; it would hit just as often, and measurably harder. The eight-frame hive, on account of its hindrance of brood-rearing, defeats its own object—contraction—to get a large force of bees early into the super.

If we admit that ten-frame hives give more honey, then more brood must be produced. I do not believe that more honey will be stored, or more combs be built, simply because there is vacant space; nor will the queen lay more eggs simply because there is a large area of comb; but the work done in the ten-frame hive may exceed that done in eight frames because of inadequacy of the eight; and because eight combs of brood is enough for a colony it does not follow that that number of combs in a hive is sufficient for *all* demands of that colony.

It has been said, that one fact is worth a bushel of theories. Theory tends to improvement: facts stand still. Facts may lead us to settle down upon a ten-frame hive as if it were perfection itself; but theory may devise a hive combining the best features of both the eight and ten frame hives.

If it is proposed to discuss the merits of hives without alteration, then I say that the ten-frame is best to breed up and retain winter stores; but the eight-frame is cheaper, handier, and will send a *given number* of bees into the sections sooner. The retention of winter stores may be preferable to farmers and others who have several irons in the fire, and who would starve the bees were it not left in the hives; but the specialist is expected to look after such things in order to enable him to perform other advantageous manipulations. The eight-frame hive is the farmer's substitute for contraction while he attends to a dairy or fruit-ranch. Said bee-keeper wishes to apply contraction during the honey-flow, but does not want to watch his bees closely during the rest of the year. By his plans he may secure the most profit from a certain amount of labor; but more labor and more profit is what bee-keepers are most in need of. When bee-keepers discuss and adopt hives best suited for farmers they had best consider the advisability of becoming farmers, for they must have missed their calling.

A large amount of honey in a hive causes the colony to build up faster, and become stronger thereby, because there are more combs of honey to be mutilated by frost, moisture, or other consequence, causing honey to be removed and carried to the brood-nest. Again, where there is much honey in the hive, that needed for brood-rearing is brought from the most distant points, and especially where it is liable to be pilfered by robbers. Such manipulation of honey is a constant stimulation. It is not possible for a colony to consume 30 or 40 lbs. of stores in two months' time without being stim-

ulated. Last spring I had colonies which consumed 60 pounds of honey while others survived on 10. In the small hives, where there is only a small quantity of honey, and a comb or two more are put in when the first is all used up, the honey remains entirely within the guard-lines, and there is very little manipulation of honey, and, consequently, no stimulation. Last year the lower hives in my apiary were about half filled with winter stores (I use the crosswise L., ten frames in a hive). Then a super of half-depth frames was put on, which were filled up and capped nicely. For brood-rearing the month of January in my location corresponds to the month of May in Iowa or Illinois. They began to rear brood the fore part of the month, and have taken honey from the ends and corners of those super combs, so that they are not more than half full. Some hives have six combs of brood, flying drones, and young bees by the peck. The larger the size of the frames adopted, and the more in number, the more of this stimulation; especially when the colonies are weak or starting to breed. It is my belief that a brood-nest can not be honey-bound in the spring—only in the fall, when there should be bees reared for wintering. These super combs are the same size as single-tier wide frames; and when it is surplus time I will take out the super combs and put in the wide frames of sections in their stead, so quietly that the bees will hardly dream of what has happened. The combs taken out will be tiered up on colonies which will be run for extracted honey. Habit of clustering in the super is expected to make the bees remain there after the sections are put in. Then I will shut down on the storage of honey in sections soon enough to return the combs to be filled with winter stores. Thus the sections will be all completed. It is my opinion that a better hive might be devised by combining certain principles present in both the ten and eight frame hives. How and what to combine is the question.

Florence, Cal., Feb. 5.

[You say it is a mooted question which is foremost—chaff or the space filled with dead air. Perhaps you do not remember the time when I tried to believe that dead air was just as good, and called for testimony to get at the truth. It came in so thick and fast in favor of chaff, or, rather, filling of some sort, that I think all of us were satisfied that dead air was not nearly as good. Dead air is all right providing you can get it in a space or compartment that is airtight. But this is impracticable; therefore, to prevent the rapid circulation, and the air escaping, it seems necessary to have obstructions in the way of filling, and thus prevent the too rapid escape of the warm air next to the bees.]

You say the eight-frame will send a given number of bees into the sections sooner. You are probably right; but would not six frames send them there sooner yet? By the way, what has become of the idea of contraction, that we do not hear of it nowadays? There was a time when it was all the rage.—ED.]

RAMBLE 127.

GAS FOR THE BEE-PAPERS.

By Rambler.

Mr. Pryal, having the Rambler upon his hands, felt it his duty to ramble me in various directions around the cities. Near Mr. Pryal's were many beautiful residences, and ample grounds laid out in a paradisaical sort of way. The owners were men of wealth, millionaires; here a grotto of rockwork covered with ferns and flowers, and running water, a beautiful plaything costing only \$3000; there a copper affair made in imitation of half of an immense

time ago; and though he is now out of the business, residing with a daughter here in Oakland, he still retains so much interest as to be a subscriber to GLEANINGS.

Our call was of such a pleasant nature that Mr. N. returned it the next day, and sojourned in our camp for awhile. Mr. Pryal, with camera in hand, gave us a shot while Mr. Wilder and I were enjoying our noonday meal, and a very good photograph of Mr. Norton, leaning against our wagon, is shown.

Immediately after dinner we all started for San Francisco, to make a call upon Mr. Harry L. Jones, a brother bee-keeper. On the way

CAMP ON TEMESCAL CREEK. NEAR PRYAL'S.

sea-shell; the cost of this plaything was \$2000. Across the way is an estate formerly owned by J. Ross Browne, who, when in this life, was a genial writer and traveler. The residence and grounds are fitted up in oriental style, or like a Chinese pagoda. There are quite a number of bee-keepers in a small way around the cities of Oakland and San Francisco, but not much attention is given to the industry as a business.

Our first call was upon Major P. L. Norton, not only a veteran bee-keeper, but a veteran of the war, as will be seen by the handle to his name. Mr. N. is from Lanesboro, Pa., where himself and son were successful apiarists. Mr. N. imbibed the love of the bee in boyhood, and has never lost it. He invented a self-spacing frame that was illustrated in GLEANINGS some

across the bay Mr. P. informed me that Mr. Jones, besides being interested in bees, was a gas collector. Now, imponderable substances, such as electricity, etc., were always a mystery to me, and I said to Bro. Pryal, "What on earth does he do with the gas when he collects it?" "Well," says Mr. P., "this gas business is a very deep question. Ask Mr. Jones about it; he will give you full information."

Mr. Jones lived then away out near the Golden Gate Park; and after we left the cable car we had quite a climb up one of those steep streets for which the city is noted. The ocean breeze comes up here howling from the Golden Gate, and loose things go flying through the air; so the San Franciscans, when they speak of their bracing climate, mean much—its brace

against the wind; and that is not all of it: the evenings are so cool, even in August, that when we were pressing the streets with our feet an overcoat was not an uncomfortable piece of clothing to wear.

We found the Jones residence, and I could not make much of a demonstration over his condition. I had to be decorous, you know. Mr. Jones is a benedict. The chains, however, seem to be worn lightly upon his genial nature. The chief attraction in the neatly furnished room was two bright children—a pretty little girl and a bright-eyed curly-headed boy. The latter lay upon a rug, kicking up his heels in childish glee, and showing to good advantage his first pair of trousers. I could well see that Mr. Jones was proud of his benedict condition, and, of course, I would say nothing to mar his pleasures of married life, and to make him wish himself a roving bachelor.

Mr. Jones has 22 colonies located within a little grove of gum-trees. Every bee-keeper knows that a high bracing wind has a very bracing effect upon his bees; it puts them in a valorous mood. Owing to the amount of bracing climate that the Jones bees were subject to, they were sort of educated up to a high pitch of aggressiveness. Upon our arrival upon the borders of the apiary the picket-line of cross bees commenced operations; and upon a closer approach, if we passed the entrance of a hive, hordes of bees would tumble over each other to get at us. Mr. Jones's smoker did not send out a sufficient volume of smoke, and we all made for the brush with alacrity; and, after peering through the leafy cover of a gum-tree at Mr. Jones over his pet colony, we all decamped. The place was too hot for us. The stings we had received were longer than usual. (Note the fact in favor of a bracing climate.) If I remember right, Mr. J.'s bees were in the Dovetailed hive and Hoffman frames. That sting back of my ear made me "disremember." We found it more pleasant to talk bees with Mr. Jones in his house. Mr. J. said, with a smile, that, when the bee-fever struck him, he posted right off and bought a foundation-mill. Of course, that would appeal to almost any sensible man. You can not build properly until you lay the foundation; hence the mill before you own a colony of bees. So Mr. Jones was a happy man as he lugged his foundation-mill home under his arm, and dreamed of grinding out tons of honey for the San Franciscans. Mr. Jones is something of a hobbyist, and has run the camera hobby from A to Z. Several other hobbies have had their turn, but the bee-hobby seems to have come to stay, as it always does when it gets possession of a man.

Mr. Jones has always lived in the city, and expressed himself as heartily sick of sidewalks and rows of brick and mortar, and gas. He longed for the free and open country, and a

bee-ranch, and is taking such active steps in that direction that, ere many weeks, we may expect to hear of him as a full-fledged bee-master.

"Oh!" said I; "Mr. Jones, I understand you are a gas collector. What do you do with that sly imponderable substance?"

"Why, Mr. Rambler, I send it back east. You see, California gas is the best in the world. Just see how our towns have grown under a liberal supply of gas. Ours is the genuine boom gas. Why! there are hundreds of towns in this State that are all gas. You go out on the desert and see little white stakes marking out lots, streets, and avenues. Still, that appears on paper as the beautiful town of Vistablendé—all gas, and too much gas in those cases."

"Well, Mr. Jones, I should like to know who wishes California gas, back east."

"That's a leading question, Rambler; but seeing it's you I will tell you. I send gas to merchants—notably, ready-made clothing, dry-goods, horse-trainers, and a large amount to patent-medicine dealers."

"Well, now, Mr. Jones, do you send any to our friends the bee-keepers back east?"

"Ha! ha! Yes, all of the bee-journals order more or less. There's the Roots and Hutchinson, who order temperately. York's orders are increasing; Alley orders largely, and I have strong hopes in that line for Heddon; he is doing remarkably well for a beginner. Canada bee-keepers would like our gas, but old Hingland has such a grip there that it's hard to let go of the inferior quality. W. F. Clarke gets

a little of our gas occasionally, and improvement in his writings is noticeable. Somnambulist, of the *Progressive*, orders largely; and Hasty, of the *Review*, has a regular monthly bag. But there's Jake Smith. He gives me big orders right along. Why, I believe that fellow is like some of the above towns spoken of—all gas."

"Why," said I, "Mr. Jones, Jake has skipped the country. He does not write for the papers any more."

"Yes, he does; but it's under another name. Let me whisper in your ear" (and we hitched our chairs together in the corner of the room).

"Ha! ha! Is that so? Then Jake Smith is—"

"Sh—! don't mention it; but he is the best customer for gas all the same. Now, Mr. Rambler, while we're on the subject, don't you wish to buy some for your Rambles—tone 'em up a little, you know?"

"No, thank you, Mr. Jones. I never used the imponderable substance, and don't believe I shall use it now. No, sir; no gas in Rambles."

It was quite late when we returned to the Oakland side of the bay; and as we rested in our camp it was sweet dreams of fair women and laughing-eyed children that floated through the dreams of the Rambler.

QUEENS TO FOREIGN COUNTRIES.

SOME OF THE DIFFICULTIES, AND HOW THEY HAVE BEEN OVERCOME.

By G. M. Doolittle.

As will be found in back volumes of *GLEANINGS*, I sent the first queen that ever started in the mails, from this country for Australia or New Zealand, in August, 1884, the same arriving in New Zealand alive, although she died soon after landing, before she could be introduced. My next trial proved a failure, as, at that time, I did not know the running time of the steamers plying between here and that country. The partial success of this first venture, if it might be called a success at all, stimulated me to experiment further along the line of shipping queens to foreign countries, and the next tried was to Scotland, Ireland, and Jamaica, West Indies. About fifty per cent of these went alive, which gave me still more faith in the project of mailing queens long distances. That my faith might be strengthened, and that I might establish something definite in regard to the matter, I began experimenting here at home. I went to work and made cages of different patterns, provisioned them to the best of my knowledge, placed in them bees of all ages, together with a young vigorous queen, and then placed these cages in my shop and elsewhere, coming as near the conditions which they must meet in going long distances as was possible, hoping to prove something definite in the matter. Some were

placed in the loft to the shop, where they would be in a sweltering heat a part of the time—this to represent what they must endure in passing through the torrid zone, while others were left out in the sun, and still others in a fairly comfortable place in the shop. Some of the cages were provisioned with honey, but the most of them with the Good candy. Some were wrapped up closely in a leather bag, to represent what the mail-bag would be to them, while others were not wrapped up at all. Some were tossed about nearly every day, and even thrown across the shop, to represent the throwing of mail-bags off a train while in full motion, while others were handled only once a week. Some cages were thoroughly ventilated, and others allowed very little ventilation. In this way I sacrificed some 15 or 20 queens, and conducted these experiments through several months. The result was, that the average living time of the bees and queens was about 18 days, while no queen in those tried lived over 26 days. The workers would usually begin to die in from 12 to 20 days; and after they commenced to die they went rapidly. After all the workers were dead the queen would soon die; and in no case, during these experiments, did I have a queen live over three days after all of the workers were dead. From these experiments I settled down to the conclusion that it was useless to try to send queens by mail where the trip would take more than 26 days, so did not try to send them a greater distance than 3000 or 4000 miles.

In 1891 I received several orders for queens from Australia, the parties saying, "Try the thing and see how it will turn out." I did so, and the result proved far better than any of my experiments here at home, for I succeeded in getting over there alive about 65 per cent of those sent, none of which were less than 36 days *en route*, this being ten days longer than the best one in the experiment lived. Here is something I can not understand—why bees and queens will live longer while in transit than they will when being experimented upon, and not traveling half a mile, all told.

In one of the cages sent in 1891 I put 35 bees, and every bee in this cage, excepting two, arrived at its destination alive, being 38 days in the cage. This success of 1891 gave me new courage; so when the time came to send queens to Australia in 1892 I started them with quite an assurance of success; but, lo! when the reports were all in I found, instead of 65 per cent alive, or better, as I had hoped, that 35 per cent was the best I could bring the figures to, while the results of 1893 came near discouraging me entirely, as that year 8 per cent was all that reached their destination alive, in spite of all the pains and precaution I took in putting them up. During the spring of 1894 I put considerable thought into the matter, as I had quite a good many orders for queens from New

Zealand, New South Wales, Queensland, Victoria, Tasmania, and Western Australia to fill. One day it came to me in this way:

You know, Doolittle, when you used to give bees candy for winter stores, they would do well on it as long as there was honey in the hive to help them a little; but when the honey was all gone they would often die with plenty of the candy left. Then, again, it has been reported to you that, where the bees had arrived dead, they were almost always daubed with soft and sticky candy, the same becoming too soft to stay in the candy-apartments for some reason or other; and upon thinking these matters over it came to me that I should put into the cage a small piece of comb, the same having a few cells of unsealed honey, and the rest empty cells. The cells of honey would help the bees liquefy the candy were it too hard; and should the candy become too soft, then the bees could lick it up and store it away in the cells instead of their becoming all daubed over with stickiness, which is always sure death to bees; besides, it would make the cage more homelike.

From the above I concluded to put such a piece of comb in every cage, and did so, after first allowing the bees of some hive to lick and clean up all honey set to running in cutting the comb to the desired shape. As the last steamer brought in the last of the reports, I have been looking over the matter to-day and find that the results of the shipments for 1894 prove that I succeeded in landing 70 per cent of the whole sent to foreign countries alive. As this is 5 per cent better than the best ever before recorded, of course I am pleased, and fully believe that the little piece of comb put in had much to do with the success. Those sent to western Australia gave 33 per cent alive, after a journey of 14,000 miles and a confinement of 46 days *en route*. Here it will be noted that a queen—yes, and several worker-bees also—lived 20 days longer than the very longest to live in any of my experiments; and the report says that the cage and bees were clean and nice, with stores for 15 to 20 days longer.

But there is another item which I wish to speak about before I close this already too long article. It is this: None of the parties shipped to knew that I was going to put the piece of comb in the cages, so the thing drew out many remarks and comments in the reports. Among others, two asked why that piece of comb, and whether there was any brood in it when I started it. Others said I put in too many bees (I generally put in from 25 to 30), and advised putting in not over 12 to 15. Putting these two items together, I think I see something else to our benefit in shipping queens to foreign countries in the future: and next season I shall try not only putting in the comb with a little unsealed honey, but make a cage so that I can put in a bit of comb containing from ten to fifteen unhatched bees in it, they being at a stage

of advancement sufficient to show color in their eyes, so they will hatch in two or three days after starting. Something pointing toward the success of this lies in the fact that I sent one queen by express to Australia, putting in about 70 bees, and brood nearly ready to hatch, to the amount of about as many more bees, after hatching. Through some fault of the express company this cage did not catch the outgoing steamer, although started in good time, so it lay over in San Francisco, Cal., till the next steamer, thus making the time 64 days from the time the bees and brood were put in the cage till the queen was taken out at her destination, and, much to the surprise of both myself and the one who ordered them, the queen and about a dozen bees were as lively as crickets when they arrived, with all brood hatched out of the comb.

As many are interested in the shipping of queens to foreign countries, besides myself, I have given in time these things looking toward greater success, so that any who wish can take advantage of them during the coming season.

Borodino, N. Y.

[During the years 1891 and '92 we, like yourself, were much more successful in sending queens to Australia, and we were almost on the point of guaranteeing safe arrival, but we thought we would wait another year. That year, 1893, a very much smaller per cent went through alive, and the next year was but little if any better, if we except the latter part of it. But since using Good candy, made of honey and coarse granulated sugar, we have had much better success. How we succeeded is shown in the Kind Words department in this and the previous issue. We shall try, this spring, a little sealed honey with the Good candy, and shall await the outcome with much expectation. When you make the cages large enough to take in candy, sealed honey, and a little brood and 70 bees, are you not in danger of exceeding the limit prescribed by the postal regulations as to size and weight of cages?—Ed.]

ALFALFA AND SWEET CLOVER.

PAYING CROP IN TEXAS, WITHOUT IRRIGATION.

J. D. Givens.

Five years last October I sowed five acres in alfalfa. I broke the ground in September, with four mules hitched to a sulky-plow; then I harrowed it till the ground was in as fine condition as I could make it. I sowed 30 lbs. of seed to the acre, then harrowed it over once, and got a good stand. I cut three crops of hay the first season, and four every season since, yielding from one to two tons per acre, each cutting, and this without irrigation. As a grazing plant it has no superior. I pasture it from September to March, and it is, without question, the finest hog-pasture in existence.

Cows prefer sweet clover. I have two acres of this adjoining the alfalfa. The gate opens just on the line between the two. I soon noticed the cows turning to the sweet clover. I then noticed very closely; and since that time,

without a single exception, the cows would first turn to the sweet clover. This satisfies me that cows prefer it; but, like alfalfa, it produces the very best of milk and butter. I have tried all the different varieties of clover here. Alfalfa and sweet clover are the only two that will make a success in this part of the country. Alsike, white, and red clover will do well here a seasonable year; but these long dry summers do them up, although I have a little of each left from sowing three years ago; but they will not grow here as well as alfalfa and sweet clover. In 1893, I think half of my honey was from sweet clover. It was of a fine flavor, light in color, and of a very heavy body; this season it did not bloom.

A DEER RECORD FOR RAMBLER AND WILDER TO MATCH.

Say, Rambler, that picture of that doe on page 868, Nov. 15, looks very natural. But here in Texas we carry them on horseback, when the horse does not buck them off. We returned from a deer-hunt a few days since. Our party consisted of six hunters, a negro cook, seven horses, two wagons, and six deerhounds; we killed eleven deer. I killed four—two as fine bucks as I ever saw—a fine doe, and a fawn; brother Billie killed four—one buck that had 18 points on his horns, but rather small and crumpled. Mr. Smith killed two, and Mr. Whittaker one. We had a grand good time. On our hunt in 1893 I did the best shooting I ever knew of personally. A large doe and two yearlings ran by me together. I fired four shots and killed all three. I use a double-barreled shot-gun, so I had to reload and shoot the third one before it got out of range. On a hunt six years ago our party killed 15 deer. I killed seven out of that number. Who of our bee-keeping friends has a better record?

Lisbon, Texas, Dec. 26.

A PLEA FOR FATHER LANGSTROTH.

By Wm. Muth-Rasmussen.

I learn on good authority, that many who have been in the habit of contributing to the Langstroth fund at the beginning of each year have not done so yet; and I have reason for thinking that father Langstroth feels the omission. What is the matter, friends? Are times so hard that you can not keep your pledges? or have you forgotten that father Langstroth is still with us—old, poor, feeble, and in need of friendly aid? I know that the past season has been hard on many; but can we not lop off a little expense here or there, to spare a few dollars? Get out your A B C of Bee Culture; look upon the kind, venerable face of your benefactor, and then think whether you have the heart to omit giving your usual contribution, on which he no doubt depends for part of the necessities and comforts in his old age.

Father Langstroth is now eighty-four years

old. It is not likely that he can remain with us a great while longer. When he is dead and gone, the bee-keepers will perhaps rouse up and put a fine monument on his grave. But what good will that do him? Now is the time when he needs our help. When he is gone, his memory will live in the heart of every true American bee-keeper, with or without any monument to remind us of what he has been to us and what he has done for us. I am sure that the satisfaction of having done a kind act, where it is so fully deserved, will amply repay any one for what he may give.

L. L. LANGSTROTH IN HIS 80TH YEAR.

Send your contributions direct to L. L. Langstroth, Dayton, Ohio, or to the editor of the *American Bee Journal*, George W. York, 56 Fifth Avenue, Chicago, Ill., who will forward the money to him.

Independence, Cal., Feb. 11.

[To save the trouble of hunting up the picture in the A B C we reproduce the cut above from the last photo taken of Langstroth, and in his 80th year. Yes, indeed, I know of quite a number who have forgotten their pledges. We have kept up ours of \$50.00 regularly for 10 years, as I see by our books, and smaller pledges before that. It seems to me that all the back pledges should be made up *now*; and I know that there are some at least who are well able to do it. If Langstroth was robbed of his rights as an inventor in his prime, shall he now be robbed of his just dues in his old age, sick and infirm? I make this appeal without the knowledge, advice, or consent of Mr. Langstroth or his daughter; but I happen to know that the money would not come amiss.—Ed.]

GOING OUT OF THE BEE-BUSINESS.

A VETERAN WHO IS BRIMSTONING HIS BEES.

By T. P. Andrews.

Having been a bee-keeper for the past 25 years, and a reader of *GLEANINGS* from the first number down to the present time, it occurs to me that possibly some of my experiences and conclusions might interest a few of your readers.

For several years I kept about 300 colonies; and while my locality has not been particularly good I have had some fair crops of honey. My heaviest yield occurred in 1889, when I extracted $7\frac{1}{2}$ tons. I have occasionally had a more valuable crop than that, of comb honey, although of less weight. And now in view of the changed conditions in this locality I have come to the conclusion that the chance for profitable honey-producing is about past, and that I shall have to retire from the business.

To particularize a little in regard to changed conditions, I will state that, so far as I know, I have never had a pound of surplus honey from clover or basswood gathered here, and about the same might be said of buckwheat. Our honey comes mainly from Spanish needle, after Aug. 25, with an occasional light yield from heartsease during the two weeks preceding that date. Honey-dew comes along about once in three years, and saves some of the expense of summer feeding.

When I began bee-keeping much of the land was raw prairie, producing a good deal of button-bush which afforded considerable honey in July, though rarely any surplus. Now the prairie sod and the button-bush are little more than a reminiscence, and, of course, are not, in that condition, of much value to the honey-producer. The more thorough cultivation of the lands, and the growing of a large acreage of timothy meadows, have about cleaned out the wild plants that used to keep our bees through the summer, and have made great inroads upon the heartsease and Spanish needle.

Twenty years ago many farmers kept bees, and there was quite a sale for hives. Now the bees have about all disappeared, and hives are not wanted; neither is there any demand for bees. This state of affairs is not limited to a small scope of country, but seems to prevail over several counties at least, in this part of the State.

One of the results of our scant summer pasturage is that our bees are practically non-swarmer, especially in large apiaries. Another result has been that, having little honey in the hives in summer, a drouth or a cold spell has usually made feeding necessary. Of late years summer feeding has been the rule, requiring some seasons as much as five barrels of sugar. Fortunately I have never been obliged to feed for winter, and have failed to get some surplus

but twice in 25 years. My surplus for the past five years has averaged annually only about 15 lbs. per colony of extracted honey. I have reduced, in the past three years, from 300 colonies down to about 140, without much effort on my part until last fall, when I brimstoned 55 of the least valuable of the colonies after extracting the honey. By this arrangement I can realize something from the sale of the honey extracted, and from the emptied combs.

While this may not be regarded by bee-keepers as the most desirable way of retiring from the business, it seems to have some advantages over the more common way of letting the bees starve and the moth eat the combs.

Farina, Ill.

[Certainly this is not "painting the business in too rosy colors," but it seems to me brimstoning is both wasteful and unnecessary. It would be far better to offer bees, hives, fixtures, etc., way down cheap than to resort to the primitive brimstone. "No one to buy," you say. Advertise, and find some one. Friend A., in a private note, says he is going to sell the combs after extracting. But, dear me! it is a sad state of affairs if the bees, hives, honey, and combs together are not worth more than just the honey and combs alone. Say, Bro. A., before you brimstone any more, try an advertisement offering full colonies, including hives, cheap. If the "ad." doesn't pay we will remit the charge. —Ed.]

MANUM IN THE APIARY.

LEATHER ITALIANS; NEW VARIETIES OF POTATOES; THOROUGHbred CHESHIREs, ETC.

By A. E. Manum.

Returning home from one of my out-apiaries just as Dan (my helper) was coming out of the house from his dinner, I saw a strange carriage in the yard, when I asked:

"Dan, whose carriage is that?"

"It belongs to a young man who arrived just as I was sitting down to dinner; and as Fred took care of his horse, I did not learn who he is. He and Fred are now at the table. I think he is a bee-man, judging by the conversation I heard between him and Fred."

"Well, then, Dan, you may take care of my horse if you will, and I will go right in. You may unharness Daisy, as I probably shall not go to another yard to-day if this man has come to see me. . . . Well, well! Walter Larrabee! I am surprised, truly, to see you in Bristol—not only surprised, but greatly delighted. It is not often that I have the pleasure of entertaining the president of the Vermont Beekeepers' Association."

"Thank you, Manum. You see, since we are unable to get you out to the conventions of late, where we can learn what you are doing in the bee-business, I just thought I would take a drive out here and interview you at your home."

"That is right, Walter. Here is where you will find me every day, right at home or at one

"WHEW! MY SAKES! WHAT A SMUDGE IT MAKES!"

of my apiaries. But I have so simplified the work with the bees now that I give my out-apiaries but very little time compared with what I did formerly. From three to six or eight hours per week is all the time I give each out apiary now. I find I can do as much in three hours now as I once could in a whole day—that is, I can accomplish as much.”

“I suppose, Manum, the reason for that is, you have changed your methods somewhat, and do much less needless work.”

“Yes, Walter, I am forced to do as little work as possible, in order to make the rounds. But the fact is, I have simplified the work so much in all of its branches, that, were it not for the other branches that I am carrying on—such as fruit, poultry, swine, and seedling potatoes—I could care for a much larger number of colonies.”

“Yes; I heard you were doing quite a little in small fruit, garden truck, and poultry; but I did not know you were interesting yourself in originating new varieties of potatoes; and, really, I should never have thought of your going into the swine-breeding business. How many have you now, and what breed have you?”

“I have only 40 head now, as a starter, and am breeding thoroughbred Cheshires. I am doing it more for the fertilizer I shall get than the profits from the meat or from sales of breeding-stock. I find that berries require very rich soil to do well, and I therefore thought I would try the experiment of making my own fertilizer rather than buy it. As to the seedling potatoes, I have done quite a bit of that work one time and another; and although I have brought out some very fine varieties, I never pushed any to the front until last spring. The few varieties that I now have are proving so very remarkable that my friends who have tested them advised me to push them. I enjoy such work so much that I make crosses every year; but it is only occasionally that I get a good choice variety of potatoes from the thousands and thousands of seeds I save from the potato balls and plant.”

“Dear me, Manum! it makes my head dizzy to think of all this. How in the world can you do so much with so little help as I see about?”

“Oh! by working *every day*, from daylight until dark. Let me tell you, Walter, when a man is doing such work as he enjoys, he does not mind the long days; in fact, my experience is that sometimes the days are not nearly long enough. Wife says, if I had the power that Joshua had, when I get to experimenting, there would be no sunset. Now, Walter, we will adjourn to the apiary.”

“Yes, I want to see ‘Manum in the apiary,’ and the leather-colored Italian bees.”

“Just wait a moment, Walter, while I get my smoker, and I will open a few hives.”

“Hurrah! you have one of the Crane smokers, I see. How do you like it, Manum?”

“There, there! how do *you* like it, Walter?”

“Whew! my sakes! what a smudge it makes!”

“Yes; when I want lots of smoke, nothing will produce it equal to a Crane smoker. The only fault I find with it is, that it is a little heavy. It is so much larger than my old one that it seems a little awkward to me; but I am getting used to it. When I first got it it would not work at all; hence I did not use it for a long time. Finally I took it all to pieces and fixed the valve, and now it works all right. I think Mr. Root ought to be more careful about sending out imperfect work.”

“Are these bees your leather-colored ones? They look rather dark.”

“Yes; these are pure Italians. This is one of my best colonies, from which I propose to rear queens another year. There is the queen. You see she is large, thick, and stocky. Such a queen will produce large hardy bees, as you see here. Just notice their long broad wings.”

“I don’t see where you raise your queens, Manum. I see no nucleus-boxes around.”

“No, I have not used any this season, as I raise all my queens in and over full colonies. Here you will see how I do it. First, my queen-cells are all built in full colonies, and at the proper time they are cut out and placed in these little queen-cell cages, which I call my queen-nursery. When one hatches she is introduced into one of the apartments here, over a full colony. I take a half-depth brood-chamber, divide it into four apartments, or nuclei, tack a sheet of wire screen on the bottom, and place it over a full colony. Each apartment is given three combs and a few bees, which forms my queen-breeding apartments. In this way I economize heat, thereby getting better queens, which are fertilized younger than in a little box by themselves.

“I am sorry to have you go so soon. I only wish you would stay all night. You will please give my regards to your good father and mother, and to your brother John when you write him.”

Bristol, Vt.

[A few of last year’s pattern of valves went out defective; but now every smoker is inspected by our apiarist before it goes out. Besides, the new form of valve is more perfectly constructed.—ED.]

BEE-PARALYSIS IN FRANCE.

A CRITICAL EXAMINATION OF THE SUBJECT,
CONDUCTED BY

Ph. J. Baldensperger.

We never had any trouble with bee-diseases in the Orient, and I am wholly ignorant of what foul brood looks like, except from accounts read in books or bee-periodicals. Consequently I was never troubled, and so have not examined the matter. Last spring a case of bee-paralysis

presented itself, and I was quite puzzled to make out what it was. I will relate the whole of my experience as I noted it down during nearly three months.

I sold a hive to a gentleman about two miles from my apiary, in July, 1893. The hive was put on his premises, very near the sea. The queen was an Italian, crossed with an Algerine drone. In October, '93, the bees gathered about 30 lbs. of surplus honey from a kind of *Rosaceæ*, so I took about 20 lbs. In January, 1894, I visited this hive, and another of my own which I had also put up very near the sea—but a mile apart. They were both in fine condition. I had no time to look at them till March 4th. Then they were getting on wonderfully. But I noticed at hive No. 1 (the one I had sold) numbers of dead bees in front. I took up the most of them—weighed them, and found about 5000 dead bees. The hive then had nine frames of brood. I could not make out what the trouble was. A cold east wind had blown a few days previous to my visit. The alighting-board was out of place, and the neighboring pine-trees had strewn the ground with yellow pollen, looking like sulphur. I supposed death came from one of the above-named causes; but I asked Mr. G—, the owner, if he had anybody round about him who might have poisoned his bees. His answer was in the negative. March 19th I revisited the hive, to find, to my great astonishment, only six frames of brood and about 3000 dead bees. I watched the bees then very closely, and found some flying in readily, while some dropped in front of the hive or on the alighting-board, with the body as full as a well-filled bee can be; but it simply remained there as if stunned, and died outside the hive after vain efforts to enter. The bees in the hive did not like to receive the weak ones, or those showing signs of the sickness—i. e., an unsteady gait and a swollen body. I could now only say that something was the matter, but not what. I examined all books treating on “bee-diseases;” found the nameless bee-disease, bee-paralysis, and the *Maikrankheit* (May sickness) of the Germans. Witzgall says the disease disappears after a heavy rainfall. I watched this, as it resembled it in many respects, but not in all; namely, it did not come on in May, and did not go after several heavy rainfalls. I wrote to Mr. Thos. W. Cowan, who advised me to treat with naphthol beta, but said, at the same time, that it is never so serious in England as the case reported. Meanwhile a “fixiste” (we so call the old-style bee-keepers in France) reported a case that occurred several years ago, and attributed it to the bees having sucked the sulphate-of-copper solution which they sprinkle on the vines, in search of water. This did not hold good, as the bees in No. 1 had plenty of clean water in the vicinity, and the sprinkling business was not then carried on. We looked for a poisonous plant, and found the *Euphorbia den-*

droïdes, a plant growing north and south of the Mediterranean, and used in Algeria to intoxicate fish; but after several hours in roaming about the mountains I found one single bee, which did not stop long enough to let me examine; besides, this suggestion did not hold good, as the plant also grows near my home apiary and other out-apiaries.

On the 5th of April Mr. G. wrote to me, saying his neighbor sprinkled his rosebushes with the above-named sulphate, and he believed that to be the mischief. Finally, on the 11th of April I had the hive brought to my house, and I put it among several other hives on the house-top, where we have a flat roof. On the same evening I counted 205 dead bees. April 12 I counted 240 dead bees in the evening; April 13, 250 more in the evening; April 14, 240 more in the evening.

It seems to me that the young bees hatch as fast as the old ones die; for since March 19 the six frames of brood have kept going.

April 15 I counted 240 dead bees. April 16, rain all day. Dead bees are still being thrown out and washed away. As often as I go there I could gather about 150 dead bees. The excrements are dark yellow, and the bees void these with great difficulty. Evidently it is a bad case of constipation.

April 17. I am testing Witzgall's sayings—241 dead bees—and all about the neighborhood dead and dying bees of this hive are found. Who can tell how many die daily far away?

April 18. About half a dozen were thrown out last night. Rain again all day, so that I can not examine.

April 19. Fine weather—no dead bees till 8 o'clock. Alas! again 240 by night.

April 20. Seven dead bees this morning—only 97 dead all day. The bees seem to be getting better; took a frame of brood and gave it to hive No. 85.

April 21. This morning 13 dead; 200 during the day; rainy.

April 22. At 9 o'clock this morning, about 50 dead. The bees are remarkably active in getting rid of the dead, and they carry them far away, so I can no more count the real number of dead; still 6 frames of brood.

April 23. Cloudy; 54 dead gathered.

April 24. Cloudy; 125 dead gathered. The frame given to No. 85 has no effect on the bees of that hive. The disease is not contagious—at least, it does not extend to the brood, if this disease is the “mucorine,” described by Witzgall.

April 25. Cloudy; 102 dead bees.

April 26. Inside the hive it looks pitiable, although they keep up six frames of brood, the mother laying continually. The bees now cover only the six frames; and in spite of the daily births, amounting to about 800, the hive has lost nearly 3000 bees, or 250 daily. The births are equivalent to what was lost on the flight. There is no more fall honey left in the hive,

which we suspected also. The bees now seem too weak to keep the hive tidy. They empty their faeces in the hive. I transfer them to a fresh hive—bees, frames, and all. About noon I counted 303 dead bees, inside and outside; from noon to nightfall, only 7, having no more honey. I presume the disease germinated in the food.

April 27. Cold and windy; 35 dead bees.

April 28. Again I change the hive; found inside about 385 dead bees; fed them honey and salt and naphthol, just enough to give the honey a taste; took again 38 dead bees.

April 29. Found 23 dead bees this morning. The bees seem vigorous, the disease going; at noon, 97 dead; evening, 25, thus making 145 dead to-day; fed again naphtholined honey.

April 30. Counted 33 dead to-day.

May 1. Counted 165 dead to-day. The disease is not going at all.

May 2. About 20 dead this morning; is it increasing? 143 by night; exchanged two frames of brood with No. 106, Algerian, to see if the disease is contagious or in the brood.

May 3. Counted 43 dead bees.

May 4. Counted 35 more dead bees to-day.

May 5. Counted 53 dead bees.

May 6. Counted 54 more dead bees.

May 7. Mortality is going on. The mother is laying, and is a beautiful insect, still keeping up her six frames—no progress and no decrease; fed 2 lbs. of salted honey—boiled; counted again 254 dead bees strewn about, not counting the numbers the bees carry away without control; bees hatching in No. 106; no disease spreading; in No. 85, given April 20, the bees are healthy; took away the mother of hive No. 1.

May 8. Counted 240 dead; May 9, 27; May 10, 54; May 11, 63; May 12, 20; May 13, 15. Divided the hive in two; plenty of cells. May 14, counted 10 dead. Bees build a piece of drone comb. May 15, counted 10 dead bees; May 16, 9; May 17, 5; May 18, 4.

The divided colonies seem better than before. Is it because of the division? Bees of both hives are gathering orange-blossom and pollen. The bees given as brood to No. 85 on the 30th of April are at work, without having communicated the disease up to date; bees at work there several days. Hive 106, which received two frames of brood May 2, which has been working since the 16th, show no disease; but the exchanged bees of 106, in the diseased hive, have been at work since the 14th of May, and show signs of the disease—consequently I can say the disease is contagious, but only from adult and field bee to adult and field bee.

I received GLEANINGS for May 1, 1894. Rambler relates, on page 371, very much the same thing I experienced here. Mr. Douse says that there the yellow bees are apt to have the disease. He is right so far. A Palestine colony far away from the diseased one and from the experiment hives has the disease, but to a very

slight extent. Mr. McFarty believes that the drones propagate the disease. I have not tried that. The diseased hive had drones in March, but has lost them all now. They died almost immediately after the division of the hive, on the 13th and following days. I read in GLEANINGS that it is worse than foul brood. The disease is disease is different with us. I tried every way to communicate it to other hives. It is not contagious. The four hives standing a few feet apart have had nothing, and they have been standing side by side for more than a month.

May 19. Young queens hatch in both hives; the bees kill them all but one; no dead bees in either hive.

May 20. About a dozen dead early this morning; about 11 o'clock, rain; afternoon, gathered about 40 dead bees.

May 21. Counted 54 dead bees.

May 22. Counted 25 more dead ones.

May 23. Rain; no control.

May 25. Counted 25 dead bees to-day.

May 28. Counted 30 more dead bees to-day.

May 29, 30; June 1, 2—four days, no time to look after the bees.

June 3. Counted 50 dead bees; June 4, 25; June 5, 25; June 6, 15.

June 7. No more dead, and now the hive is finally rid of disease; took the hive up the Alps with the others. The bees in it could get some honey, but did not build up; still, it is well, and I sent it back to its owner in November. In December I revisited the hive; found it all right, in good condition; three frames of brood, and about 7 lbs. of honey; a population of about 10,000 bees.

The Palestine hive had the same, but much less extensively. I fed it with salt and naphthalined honey. It did not seem to affect it, either for good or bad. Not being at the house, I could not follow hive No. 1 daily; and, besides, the business of counting bees was next to impossible, as the ground round about was uneven, and covered with bush and herbs; but what I did, perhaps saved the hive. I picked all I could see—every diseased bee; for, besides the drowsy appearance and swollen body, the fuzz on the thorax falls away or is pulled off; anyhow, it was quite black, and the sick bee is easily distinguished. I kept picking them out every time I visited the hive, till there were no more left. The hive is again thriving with the others. With the same mother, they too gathered only their winter stores.

In conclusion, this is what I found: It was not the quality of the honey gathered in the fall; it was not exposure toward the sea; for another hive, placed near there, with the same plants to visit, and the same exposure, did not have any trace of disease. It was not want of food, as they always had plenty; the queen has nothing to do with the disease; the disease is confined to adult bees and fielders; they do not

communicate the disease to neighboring hives. The only thing I can suppose likely to have produced the malady is that the hives in question were too well protected against the cold — no airing on top, the sweat causing the mischief, the disease being communicated to only such bees as receive food from diseased bees, or such as pick up the faeces dropped inside the hive by diseased bees, thus acting like cholera, but only on such individual bees as touch the excrements.

I should be very glad to hear from our scientists. This is what I myself believe; but I may be altogether wrong. I have here given the facts picked up daily, and my thoughts thereon.

Nice, France, Jan. 5.

[In many respects the symptoms above given correspond with those of the same disease in this country; but it is a noticeable fact that they seem to vary under different conditions and in different localities. Mr. Baldensperger thinks the queen has nothing to do with it. The majority of testimony so far received seems to show pretty decidedly that she does.—Ed.]

BEE-PARALYSIS HEREDITARY.

A REPLY TO S. A. SHUCK.

By T. S. Ford.

I read Mr. Shuck's article on p. 54, and write to say that I am quite sure he is mistaken in his conclusion that bee-paralysis is not infectious; and I hope that you will adhere to the policy lately pursued by you in GLEANINGS, intended to induce queen-breeders to destroy all infected colonies. It is a step in the right direction. All the writers on this subject that I have noticed, who live in the South, like Mr. Getaz, of Tennessee, agree that it is a very serious disease. You know my reasons for concluding that it is infectious. It spread from a single diseased colony, purchased by me, to every colony that I had except two, in one season, assailing those nearest first, and then it extended from hive to hive as they were arranged in order on the benches; and to put the matter beyond peradventure, when I introduced a queen from one of my hives to a colony of blacks in my brother's apiary, bee-paralysis promptly developed with the appearance of her progeny, and this though she was, to all appearances, perfectly healthy when introduced, and the colony she came from had apparently made a perfect recovery from the disease. Following this, and after the robber-bees had cleaned out this hive, my brother had a well-marked case of the malady among his blacks; and, acting on my suggestion, he promptly got rid of the disease in his apiary by brimstoning the whole colony, since which he has had no more of it.

Mr. Shuck's article was very interesting to me, though I can not agree with his deductions. The truth is, so far as actual knowledge is concerned we are just where Miss Gayton and Mr.

Cheshire left us. We know that, back of the symptoms of the disease, as in the case of cholera, consumption, erysipelas, and other diseases of the human subject, there is a bacillus; but how this germ gets from one bee to another, we don't know. It is a matter for the microscopist. It is true, that the infection does not seem to spread readily from using, in a healthy colony, the combs from an infected one. My own observation in this respect is in unison with those of others as reported, with the exception that, finally, all of my colonies got the disease at last; but whether from infection communicated from the combs, or through diseased bees entering the wrong colony by mistake, or by means of robber-bees, can not be told. Considering the crowded state of the hive, and the close intercourse of its inmates, it is rather strange that the contagion does not sweep away the whole population at once. It is a fact, however, that many hives show a few bees having the first symptoms of the disease, that do not reach the worst stage. In many colonies, bees that are hairless and shiny can be seen with quivering wings, staggering about, that go all through the season without any great mortality. At this stage the guard-bees are still on the lookout for sick individuals, and they pull and haul them about and pluck their hair off until they are at last ejected from the hive and are too weak to return. But there comes a time when the disease becomes epidemic, so to speak, when the guards cease to hustle the sick, and the swollen, bloated bees begin to appear, and the guards have plenty to do to carry out the dead, who are normal as to color, but most of them enormously distended. At this stage the bottom-board is sometimes spotted with the yellow faeces of the sick. In cholera, typhoid fever, and other infectious or contagious maladies, the chief source from which the contagion spreads is the dejections. May it not be true of this also? The colony has invariably perished when this spotted condition of the bottom-board has manifested itself.

Mr. Shuck thinks that sour honey may have something to do with the production of the disease. It may aggravate it, but the real cause is the specific germ that can be derived only from some other infected individual. Harvey's maxim was, *omne vivum ex ovo* (all life is from the egg); and the same principle underlies the propagation of disease-germs. They do not generate spontaneously. Bees have been kept in this county since its first settlement, and there was never a case of bee-paralysis until my unlucky importation. Yet if there is any sour honey now produced in a natural way, it certainly was here before; but it never made bee-paralysis before. I hope you will stand fast in your position, and do what you can to protect the inexperienced from being the victims of some careless queen-breeder who thinks the disease a trifling one.

I have come to think that humidity may have something to do with the fostering of the malady. I have two colonies that came near being exterminated last spring; yet when warm dry weather came on they built up rapidly and became strong enough to lay up stores for winter. With the wet weather we have had of late, the old symptoms have returned, and they are nearly as bad as ever.

We have had a good deal of steady cool weather so far, and there is not a flower to be seen; yet, going among my bees yesterday, Jan. 24th, they were seen bringing in immense loads of what appeared to be pollen of rather peculiar color. The same day a neighbor remarked that my bees were swarming on his cotton-seed meal, and then I recognized the peculiar color as that of cotton-seed meal. They certainly bring in the most enormous loads of it. I wonder if it will serve their purpose as well as pollen. I am going to buy some cotton-seed meal and give it a trial.

There is every indication that we are going to have a fine honey crop this year. There has been so much cold weather that it is almost certain we shall have no bloom killed by frost. It will take a month of warm weather to start the trees to budding, by which time we ought to be measurably safe.

By the way, a singular and most unfortunate thing happened in our neighborhood last fall. An unusual quantity of sugar-cane was raised, and the making of molasses lasted nearly three weeks, during which time the bees were drowned by the peck in the cane juice and in the boiling syrup. Our stocks were greatly reduced in numbers by this occurrence. If I live till next year I intend to close up the entrances with wire cloth during the grinding season.

I am going to try sulphite of soda in syrup, for bee-paralysis. It is said to be a good germicide.

Columbia, Miss., Jan. 25.

[And here is another article that seems to uphold pretty well the position of Mr. Ford.—Ed.]

BEE-PARALYSIS PRIMARILY FROM THE QUEEN, NOT FROM THE FOOD.

I notice what has been written on bee-paralysis by different ones. In 1877, while in Milford, Wis., I bought a queen of an eastern breeder. She was very prolific, and produced fine bees. After her bees were two or three weeks old they would swell up and shake and tremble, and crawl about until they died. In the fall I added a small swarm to the diseased one, and next season she filled her hive with bees, but all the while they kept dropping off with paralysis. I reared six queens from her, and every one of them produced bees with paralysis. I let no drones fly from this queen, so all the young ones were mated with good drones. I sprayed them with salt and water many times; I also sprayed with a mixture of carbolic acid and water, but all to no purpose. All remedies failed. Some-

times there would be a pint of dead bees at each hive. I also noticed that, as the queens grew older, more bees died from each hive; and if I had not added frames of brood from other hives they all would have died. I kept them three years; and as I concluded there was no redemption for them I killed all the bees and queens, and put new swarms on the combs, and I have never seen a sign of it since; therefore I believe the fault lies in the queen, as no paralysis ever appeared from the combs where the bees had been killed. I do not think that sour honey has any thing to do with it. I have also learned from the queen-breeder of whom I got her that his whole apiary was affected with it, and that the drones from such diseased queens would show the disease in their progeny, even when they had been mated to a healthy queen.

Redfield, N. Y., Jan. 18.

J. R. REED.

BEE-PARALYSIS.

A CRITIQUE OF PENDING THEORIES.

By Dr. J. P. H. Brown.

Bee-paralysis seems to be one of those occult diseases whose etiology is beyond the ken of the bee-keeper. I have never, to my knowledge, seen a case of it, but I have read the writings of others upon the subject, with much interest.

In GLEANINGS, p. 54, this year, there is an article on the subject by Mr. S. A. Shuck, who advances the idea that it may be caused by poisonous, sour, or unwholesome honey. Now, Mr. Shuck's opinion may be considered untenable when placed by the side of so high an authority as Frank R. Cheshire, who considers this disease to be caused by a bacillus (*bacillus Gaytoni*, after a Miss Gayton, who first called his attention to it). He says these bacilli are not only in the affected workers, but also in the queen. If such be the case, then it becomes a more terrible disease than foul brood—harder to reach and more difficult to eradicate. Any germicide sufficiently powerful to destroy these bacilli in the workers or queen, by any admixture of food, would also either destroy these insects or impair their future usefulness; hence total destruction of every bee in the hive would be the only infallible remedy.

Cheshire's bacillus theory has given rise to the remedy of changing queens. This course seems to have worked with some satisfaction with a few of the reporters of this disease to the journals, while others have reported that they could see no benefit. Mr. O. O. Poppleton, a very intelligent bee-keeper of long experience, reports in *The Bee-keepers' Review*, p. 267, that he "changed queens, with no result." If Cheshire is correct in his observations upon bee-paralysis (in many other instances he has not been infallible), then, let me ask, what benefit does the infected hive receive from a change of queen? The infected workers are still in the

hive, and they would soon communicate the bacilli to the introduced queen.

Mr. C. W. Dayton, a correspondent of the *Review*, p. 272, from Florence, Cal., observes, when speaking of queens in hives affected, that "in every case I have seen, the queen was an unusually prolific layer." Mr. O. O. Poppleton says, "My nuclei with young perfect queens have suffered much more than old colonies with old queens." Now, how can the idea be entertained that a queen whose ovaries are infested and swarming with *bacillus Gaytoni*—whose vitals are being continually preyed upon by microbes—can be "an unusually prolific layer"? The idea is absurd. It would be just as rational as to suppose that a person infested with the spores of yellow fever, cholera, consumption, etc., would be physically able to perform a full day's work.

Mr. Poppleton says, "It is an exceedingly erratic disease. At times it seems to follow no rules; at other times it works in well-defined limits." Mr. Getaz remarks, in *American Bee Journal*, that "the malady is much worse some years than others, and generally much worse in the spring." Mr. Dayton says, "It usually attacks a colony about the time it gets populous enough for the surplus-receptacles." Mr. T. S. Ford observes, in *Review*, p. 240, that "the disease does no harm except in the spring and during the honey-flow. At that period the bees die in such quantities that I have seen as many as a peck of dead ones in front of a single hive. When warm weather sets in during June it disappears in nearly all the colonies, and only an experienced eye can detect it."

Sifting the various reports of the disease as given in the bee-periodicals, they all show that the symptoms of the disease vary very much during the season—at one time being very prominent; at another, scarcely if at all perceptible. These erratic conditions of the disease are incompatible with the theory of *bacillus Gaytoni*, and we must look elsewhere for a cause.

Mr. Shuck, the gentleman already quoted, says that, from his observations, he concludes "that, in some instances, this disease is the result of a poisoned condition of the honey," and that the poisoning results from incipient fermentation—not that all honey with a slight tendency to ferment is injurious to bees, but that honey in this condition will readily absorb the poisonous effluvia from dead and decaying bees or other decaying matter in the hives. Then, too, I believe that, in many instances, the honey actually becomes sour enough to cause the disease; and I fear that this is the trouble in warm climates such as that of California and the Southern States." These conclusions of Mr. Shuck are worthy of some consideration by the scientific bee-keeper; for, if the symptoms of this disease are carefully studied, they seem to point to some poisoned condition of the food

taken by the bees—it might be either honey or pollen, or both—rather than to the theory of bacillus.

We know that every kind of plant and vegetable, when in certain condition, is liable to be attacked by the spores of fungus. We know that the grape, the peach, the potato, etc., are more subject to rot in some seasons than in others. In favorable atmospheric conditions of a week's duration the fungus may develop, and the disease show itself; while with a change of conditions the disease may check or disappear. In the Report of the Department of Agriculture for 1886 the mycologist of the department observes, when speaking of fungi, that "the fungi which infest our cultivated plants, and not infrequently cause their total destruction, vie with the insect tribes in numbers as well as in the extent of the losses they occasion; and in the transformations they undergo in their development they are equally complex and often more difficult to follow. They are, for the most part, so small, and the metamorphoses they undergo are so obscure, as to call for the greatest amount of patience, and the closest study, in order to obtain any satisfactory knowledge of their natural history; and in spite of all our efforts there will frequently remain many points which must be left to conjecture. That these fungi which make themselves manifest in the plant-diseases known as 'rust,' 'smut,' 'mildew,' 'blight,' etc., are true vegetable parasites; that they are governed by the same laws which control all living organisms; and that they are propagated by specially developed reproductive bodies called spores, are fundamental truths to be kept constantly in mind in studying this subject."

These spores are conveyed by the air, and only await congenial conditions for development. They would be as liable to attack the pollen or nectar secretion as any other part, if the conditions favored, and then be carried by the bee to the hive, in the shape of diseased food, to breed sickness to the inmates.

In many portions of the South there are large plantations of melons that are grown for the northern markets. It is not unusual to find on these grounds hundreds of broken, rotten, and decaying melons, swarming with bees sucking the fermenting juice that is teeming with the spores of fungi. The effects of such rottenness on a hive of bees I can only conjecture. To say that the instinct of the bee is always sufficient to discriminate between what is wholesome for it and what is prejudicial, is all nonsense. They often visit places that are not overly nice. They will often visit poisonous flowers, for instance, the *Gelsemium sempervirens*. In GLEANINGS for Jan. 15, Prof. Cook refers to a tree in California—*Eucalyptus rostrata*—that is very fatal to bees. I admit that the bee will swerve from the dictates of its instincts only from necessity and not from choice.

I have penned the above to elicit thought, and to prompt observation. Our experiment stations should take up the subject: it is a field for the scientist. Scientific observations should be conducted at different points, and notes compared. This is the only satisfactory way to determine the cause of the so-called bee-paralysis. Augusta, Ga.

PUTTING SECTIONS INTO T SUPERS.

A GREAT IMPROVEMENT OVER THE OLD WAY.

By Emma Wilson.

It is about the time when a good many bee-keepers get ready for the year's crop, and a pretty good time to discuss ways and means. I have spent a good deal of time, first and last, in filling sections into T supers. I thought I had become quite adept at it. As I put the foundations into the sections, I piled the finished sections one above the other on a board, until I had put on as many as it would conveniently hold—about a hundred, I think. Then I would set it to one side and commence on a fresh boardful, until I had a good many hundreds piled up in that way. Then I would have to stop, and commence putting them into the supers. I never enjoyed that part of the work very much. Some way it always seemed like so much lost time. Once in a while a boardful would come to grief by being upset all in a heap, and it would require some patience to straighten things out again.

When supering I would put the super on a table of convenient height, put the T tins in place, and, by taking two sections in each hand, could fill one row across the super at a time. I really didn't see how there could be very much improvement on that plan of filling a T super.

One day as I was putting in foundation Dr. Miller stood watching me, and wanted to know why I didn't put the sections directly into the super instead of piling them on a board. I told him I had tried it a good many times, but it was very slow work. The T tins would not stay in place; and even if they did, it took too long to fit each section in place. I could set them down on a board much more rapidly. He replied, "I believe I can fix it so that you can put them into the super just as rapidly as you can set them on the board."

□ Now, I had a good deal of faith in Dr. Miller's ability to make the work very much easier, for he has a genius in that direction; but my faith was not quite strong enough to imagine he could fix any arrangement by which I could place those sections into that T super as rapidly as I could place them on a board. But he

did. If he did not quite revolutionize bee-keeping, as the stock phrase has it, he certainly did, in my estimation, revolutionize filling the T super.

He took a board as wide as the super, and a little longer, and nailed a cleat as long as the width of the board, an inch wide and $\frac{3}{8}$ thick, on one end of the board, to push the super against. Two inches from this cleat he nailed a strip $11\frac{1}{4}$ inches long, $\frac{1}{2}$ inch thick, and $\frac{1}{4}$ wide; $4\frac{1}{4}$ inches from this last strip, measuring from center to center, he nailed another strip the same size, and still another strip of the same size $4\frac{1}{4}$ inches from the last. That made three of these little strips. He nailed three other strips $2\frac{1}{2}$ inches from these strips, measuring from center to center, these last strips being $11\frac{1}{4}$ inches long by $\frac{1}{4}$ inch square. That made the board complete.

I placed this board on a box 20 inches high, at my right hand, one side of the board toward me, with the cleat at the back end. Over this board I placed this super, pushing it tight up against the cleat. As fast as I filled the sections with foundation I set them in the super. I first filled the row of six sections at the back end. It was no harder to set them there than it would be to set them on any flat surface, for you understand that, as yet, there was no T tin in the super. Now I put in the first T tin, slipping it under the whole row of sections at a clip, and do it more easily and quickly than I could have done if there had been no sections there. The sections being raised $\frac{1}{4}$ inch gave plenty of room to slip the T tin under. Now I put in the second row of sections and the second T tin, then the third row of sections and the third T tin, and, by crowding the T tin up tight, it gave me plenty of room for the fourth row of sections. When I lifted the super the sections all settled down in their places.

I can not imagine how sections could be put in more easily into any kind of super.

Marengo, Ill., Feb. 11.

WINTER IN FLORIDA.

JACK FROST AMONG THE ORANGE-TREES.

By Mrs. L. Harrison.

Mr. Editor:—"The sunny Southland, with its sweet warm air and land of flowers," has been a misnomer during this winter. We have just passed through a severe cold storm, accompanied with snow and sleet. As I sit by the table writing, and look through the windows upon the piny woods, a beautiful vision greets my eye. The tall pines, with their green branches, are decorated more beautifully than any Christmas-trees in festive halls. Their proud heads, crowned with sparkling diamonds and clear transparent prisms, are a thing of beauty, to be enjoyed once in a lifetime. There

a great white sheet of snow is loosened, and slides gracefully to the ground; yonder, a great green limb is broken from the tree by its great weight of snow and ice, and comes down to the ground with a crash.

In the early twilight of the night of Feb. 14, the large feathery flakes of snow began to descend, and fell upon the people gathering at a hall to celebrate the festival of St. Valentine. The snow was a great novelty to the young people, born and reared here, for they had never seen before more than a few flakes that melted as they fell. It continued to fall until it was three inches deep, and balls of the beautiful snow were brought into the hall, and were a source of much fun and merriment. Tiny balls were tossed at each other, in great good humor and pleasantry.

This is the third time during the winter, when there was freezing during several nights, and all winter gardens were destroyed. A few days previous to this last storm I was delighted in watching a very large colony, sailing in with heavy loads of light lemon-colored pollen, gathered from the tyty. The sweet-scented bloom of the tyty thickets yields much white honey. Many colonies have died of starvation in this locality, and more will probably follow, as this last freeze will cut off the bloom for some days.

St. Andrews Bay, Fla., Feb. 15.

BEES MOVING IN THE CLUSTER.

Question.—A neighbor tells me that the bees during winter are continually moving from the outside to the inside of the cluster, that they may have access to their honey. Is such the case?

Answer.—This story of your neighbor is one that has been told a great many times, and is based on the very reasonable supposition that each individual bee must help itself to honey directly from the cells containing the same. But, reasonable as it may appear, I am led to believe that the story has no foundation in fact. I have just been in the bee-cellar to see if I could see anything of the kind going on, and I have to report that I do not. Some of the colonies have bees hanging below the frames to the amount of one-fourth of a good-sized swarm, at least; and if such changing for honey was going on as has been supposed, certainly now and then a bee would be crawling in after honey, especially as the lowest bees would have to travel some five or six inches up through or over the cluster, to get where the honey is. But I see nothing save a big cluster of nearly or quite motionless bees, hanging and overlapping each other—each one, or nearly so,

having its head under the body of some other bee. Of course, it is impossible to see or know just exactly what is going on inside of the cluster of bees during winter; but I had always supposed, and so believe now, that bees give honey to one another; that is, the bees which are near the honey give to those under them, and these to those next further away, and so on till the last bee is reached, and the very bottom outside of the cluster. Bees are continually passing honey around during the summer, and why should they not do the same thing in winter, when it is more to their interest to do so than in summer, when all can go about as much as they please? I am aware that these things are of minor importance; but I have always believed that it is better to be informed on all the minutiae of bee-keeping than to pass any thing by as non-essential, as such a course allows us to easily drop some important point which would otherwise be brought to light.

REMOVING POLLEN FROM COMBS.

Question.—Having some combs stored away, left from queenless colonies last summer, which are pretty well filled with pollen, I should like to know how I can remove the same before I give the combs to the bees. Will you please tell us in your department in GLEANINGS how it can be done?

Answer.—Most assuredly I will tell you; for, did I have those combs, I should consider them worth almost if not quite as much as though they were filled with honey. The very best way of removing such pollen is to insert one of those combs of pollen in each hive having a prosperous colony of bees in it, in the spring; and if you have enough of those combs to go around you can consider yourself lucky. They should be put into the hive next to one of the outside frames of brood, and the work should be done in early spring on some warm day, before the bees procure pollen from the fields. This will save you all necessity of feeding your bees rye or wheat flour, or corn or oatmeal, and will be of more advantage to the bees, as it will give the pollen right where they wish it, and save the loss of bees which usually occurs from their going out in cool windy weather in search of pollen. It has been recommended scores of times that we feed our bees flour or meal in the spring, to stimulate brood-rearing; but after years of experience along this line I have become satisfied that such procedure is a waste of time and material, where the bees have pollen in the hive, and causes a loss of old bees to a greater extent than that gained in young ones. Thus you will see that these combs are very valuable for early brood-rearing, before pollen is plentiful in the fields. If you are so situated that your bees can secure pollen from the fields as soon as they can fly in the spring, so that you can not use the combs to advantage as above given, the next best thing to do is to

give one of them to each new swarm when hived. In this way the swarm is spared the pains of searching for pollen, and can devote all its energies to gathering honey; and in a few days you will find your pollen all turned into brood, if you open the hive and look. But should you not desire to use either of these plans, then I would either soak the combs in tepid water for a week till the pollen in the cells became soft so it could be thrown out with the extractor, or I would cut the combs out of the frames, melt them up, and fill the frames with comb foundation. Should you do this last you will have to render the wax from these pollenized combs by the hot-water process, or you will not get enough wax to pay you for your trouble, as the pollen in the combs will absorb all the wax, or nearly so, if they are melted in the solar wax-extractor.

MOLDY BROOD-COMBS.

Question.—I fear, by the appearances of things, that I shall have some moldy combs in the spring, as my cellar is very damp, and I can smell the moldy combs already. What will be best to do with them in the spring, should any be very moldy?

Answer.—We will hope for the best, thinking that your fears may prove unfounded. But should the combs come out moldy, probably not more than one out of four or five will be very bad. Those which have but little mold on them can be left on the hives, where they will soon dry out, and the bees care for them so they will do no harm. If any are from one-third to covered all over with mold, it is well to take them from the hive and hang them in some dry airy room till they are thoroughly dried out and needed by the bees. Don't attempt giving them to the bees while they are all wet and slimy, for nothing seems to so discourage a colony of bees as nasty, wet, moldy combs. When they get all dry, and your bees are needing more combs, take them down, and, with a rather stiff brush-broom, made from broom corn, brush them off thoroughly, but not hard enough to break the cells, when you can put them into the colonies one at a time, and the bees will clean them up so nice that, should you look for them two days after, you could not tell which they were unless you marked the place where you put them. It is best not to give any colony more than one at once, unless the colony is a very strong one. In two or three days give another, and so on till you have them all in the hive. I never yet saw a comb so badly moldy but that the bees would make it as good as ever, if the above plan was followed. Some say, melt up such moldy combs; but so far as I have tried they give very little wax when melted by any process, and none at all when melted in the solar wax-extractor, as the fiber of the mold absorbs what little wax remains.

FISH-KEGS THE BEST PACKAGE FOR EXTRACTED HONEY, AND WHY.

In your last issue of GLEANINGS, page 129, I noticed a controversy concerning the best and most practical package to put extracted honey in. If the parties had to transfer a hundred barrels into 150-pound kegs to fill orders that could not use barrels, or if they did, at a much reduced price, I think they would agree with us that the best all-around package to sell extracted honey in, in quantity, is the 150-pound pine fish-keg, costing only about 30 cents, making it the cheapest package; and, holding only about 150 to 160 lbs., it is within the reach and requirements of the small retail dealer who has not the money, facilities, nor room for handling the large barrels; and a great portion, especially of the dark and buckwheat honey, is sold to the small retail Polish Jew dealers who dispense it in small portions to their customers, who use it largely to make an intoxicating drink.

The coldest day of last week we received an order for fifty 150-lb. kegs of extracted honey, and we had to transfer it from molasses-barrels into these kegs, or lose the order. It was no easy job, as, of course, we had to do it without heating it in any way, which we have a way of doing quite rapidly, but it necessitates extra cost of kegs, some waste, and requires a lot of patience.

H. R. WRIGHT.

Albany, N. Y., Feb. 18.

[I knew your market preferred the kegs; but in other localities the barrels seem to be none too large. I sincerely hope that the demand for honey to be converted into mead or hydromel will not increase.—ED.]

THE SWEET-CLOVER PLANT; IMPORTANT TO TANNERS.

It may surprise many to learn that the sweet-clover plant is of immense value to tanners of leather. A practical tanner, an expert in his profession, assures me that the fraternity can richly afford to pay 10 cts. per lb., or \$200 per ton, for the sweet-clover plant when properly prepared for their use. A number of years ago this tanner offered me about 5 cts. per pound for the plant if I would supply him with it, and prepare it as per his instructions; but at that time I did not care to bother with the matter. There may be some practical tanners or some who may know more or less about tanning the skins of animals, among your readers. If so, and if they should wish to know how to use the sweet-clover plant, as indicated, perhaps I can supply the information. The leather thus made is said to be of superior quality—in fact, when made with japonica and sweet clover, it is equal to that which is

commonly produced from the best quality of oak-bark.

M. M. BALDRIDGE.

St. Charles, Ill.

FINDING BEE-TREES IN WINTER.

It may interest the readers of GLEANINGS to learn how to hunt bees before the snow is off the ground in the spring—especially those who live near large timber. It is well known by all persons conversant with their habits, that, after a long confinement, the bees will improve the first good opportunity to have a general fly. Such an opportunity almost always comes toward spring. There comes one or more very warm days the last of February or first of March, and the bees are out in force, so to speak. Now is the time to look for the bees that either get chilled, snowblind, or, perhaps, from age and debility, fall to the snow and are unable to rise. You may find some, twenty or thirty rods from their tree. But as you get nearer you will find them more plentiful, and immediately under the tree you will find the snow stained, so that it is not a hard matter to locate them.

Bees falling on the soft snow will soon sink by their natural heat, so that it is essential to look, at least before there is any more snow falls; and the sooner after their fly, the better. I found three trees last winter, or spring—the first two by finding the dead bees as above stated, and the third by seeing them flying on a warm day, although the snow was a foot or more deep in the woods. The first one found was a basswood, the second a butternut, and the third a large hard maple. I am satisfied that bees have but little choice as to what kind of tree they go into. I have found them in nearly all kinds of wood. I now call to mind that I have cut 8 pine bee-trees, five hemlock, three basswood, three maple, one elm, and one butternut. If they go into one kind of timber more than another it is because there is more of that kind within their reach.

Sullivan, Pa., Jan 17.

A. DEWEY.

[It would look as if winter, or the latter part of it, were just the time to find bee-trees. When found they can be marked, and, later, can be taken.—Ed.]

FEEDING BACK—A PROFIT OF 50 PER CENT.

In GLEANINGS for Feb. 15th, friend Taylor gives about the same results that I have reached in feeding back. I have fed to finish up unfinished sections for the last three years, and I agree with him that there is a profit in it of about 50 per cent. Now about the work in feeding back: Come and see me and I will show you how to feed 200 lbs. a day, and not take over an hour's time to prepare the feed and place it where the bees can get it—no daubing, no robbers, and you can tell at a glance every day what colonies are in need of a new supply of extracted honey. Just let me whisper to you, that, during the one year that I kept track of every thing, I made \$5.00 per colony during the

month of August for each colony fed. That year I fed extracted honey to 9 colonies to finish sections, and I spent only about 15 minutes per day feeding. Results, \$45.00 for the month of August. This is nearly \$2.00 per day. Doesn't that pay?

My new bee-house is nearly ready for bees; and just as soon as possible I will get two or three photographs taken, showing the outside and the inside of the building.

Syracuse, N. Y., Feb. 18. F. A. SALISBURY.

[I am not only glad that Mr. Taylor proved himself right in our last issue, but that he has such a good man as Bro. Salisbury to come forward and substantiate his statements, over an independent route. As soon as the photographs are received the engravings will be made, and will appear in due time.—Ed.]

STOPPING LEAKY GUTTERS, ETC.; ALSO SOMETHING ABOUT "SANDPAPERING" GARDENERS AND FLORISTS.

For leaky gutters in greenhouses or cracks in wagon-hubs, mix any good paint and apply with a brush, and have some hot dry sand and pour in, and work it into the crack with the brush. That will dry and not shrink. If the crack is very large it may need two applications.

Sometimes my hands chap or crack. I find a piece of sandpaper will cut off the rough piece of skin, and cut down to where the skin is hard; and then a little glycerine will heal them up quick. I find the sandpaper excellent in reducing corns and bunions on the feet. I think it far superior to cutting them with a knife.

To kindle a fire easily we have a 3-lb. peach-can, with one end out. We put in an inch or so of coal oil, and put in six or eight corncobs point down. We take one of these and lay it in the stove where it can be lighted from the draft, then put in some kindling and wood; light the cob, and you have a fire in short order.

GEO. M. KELLOGG.

Pleasant Hill, Mo., Dec. 16.

Well done, friend Kellogg. Any man who has set glass on the modern plan, with thick putty and dry sand, ought to have known what a grand cement it will be for filling up cracks in any thing exposed to the weather; but I confess it never occurred to me before that gardeners and florists needed sandpapering more than people in general. Why, since you mention it I really believe the thing I have been suffering for for years is a good thorough "sandpapering;" and I rather think it ought to be done every little while. What a beautiful world this would be if all the rough spots and corners of so many queer and curious people were to get a good sandpapering regularly! Yes, we all need it more or less. And, by the way, old friend, making such a trip as I did, and meeting such people as yourself on the way, has (or at least I hope it has) knocked off or smoothed down a good many of the rough points in a naturally vehement disposition. Your corncob idea is a good one; and, by the way, if any of the friends should run short of corncobs, the State of Missouri alone can supply the world, and I shouldn't wonder if they would put in an extra shovelful to make good measure, if you will only mention it.—A. I. R.]

EIGHT extra pages this time.

IN spite of the extremely cold weather, reports so far indicate that bees are wintering well. This is indeed surprising. When we remember that cold winters are followed by early springs, usually, the prospect so far is encouraging.

O. O. POPPLETON, of Potsdam, Fla., writes that "the frost of last week has practically wiped out all the bee-industry on the east coast of Florida for the coming two or three years at least." This is rather discouraging, coming right on the heels of such a magnificent honey season as Florida had last year.

It is with much regret that I learn that Mr. S. I. Freeborn, one of the foremost bee-keepers of Wisconsin, and, I might say, of the United States, died suddenly at his home at Ithaca, aged 62. It seems that his health had been failing for some time, and some three or four weeks ago he contracted a severe cold, which resulted in pneumonia and death. Mr. Freeborn's name was first brought prominently forward before the bee-keeping world through the Bee-keepers' Union. It seems that his bees were declared a nuisance, and an effort was made to get them out of the town; but, as our older readers know, through the efforts of the Union, of which Mr. F. was a member, the case was finally decided in favor of the bees. This was its first victory. Mr. Freeborn was not a quarrelsome man—indeed, the very opposite. He was held in very high esteem, both as a neighbor, father, and a member of the community. His son-in-law is Mr. C. A. Hatch, so well known to our readers.

MIXED JOURNALISM.

THE *American Bee-keeper* has decided to adopt mixed journalism. The size of the paper is doubled, the new matter being of a literary character. The fact seems to be, that, in spite of certain criticisms that seem to break out here and there, the bee-papers that adhere strictly to the subject of bees do not enjoy the circulation of those that have added subjects foreign to bee-keeping. Not a few of our readers take GLEANINGS simply for its religious matter, and others for the gardening department; and from the numerous letters received, it is evident that, in many of the homes of our subscribers, GLEANINGS is the *only* paper taken. One man wrote the other day, saying the times were so hard he was obliged to drop even his church paper which he prized so much; but GLEANINGS he *must* have.

But why should objection be made when we add enough extra pages every year to make up very largely for the matter that is foreign to bee-keeping? During the early part of the year, our journal is enlarged all the way from 8 to 16 pages; indeed, this number has 8 extra pages. Let's see: Last year our volume showed a total aggregate of 968 pages, or an average of 40½ pages per issue, while the regular issue is 36. Some years our volume shows over 1000 pages.

A number of years ago we took a vote of our readers as to whether they would have the extra religious matter or not. The result showed that, of those who voted, there were about 100 in favor, to one the other way. This is a conservative estimate, too, and it is to be presumed that the rest not voting was represented by this proportion. These people who criticise our course in putting in religious matter and garden topics do not seem to be aware of the fact that they are in a very small insignificant minority. If they do not like those subjects they do not need to read them, or even take the journal at all, for there are very excellent bee-papers that confine themselves strictly to bees.

ADULTERATION IN BEESWAX.

BEESWAX, as you will notice by the markets, is steadily going up in price, and we are just about out, although we are expecting more daily—enough to keep going as usual. I said we are about out. We have got some "stuff," more than we wish we had, which we bought for pure beeswax, that is beautiful to look upon; and when we bought it, it seemed to stand all the tests for pure wax. It was analyzed, however, and found to be adulterated largely with paraffine. It is now on our hands, and we do not know what to do with it unless we make the parties who sold it to us take it back or stand damages; for we would under no circumstances use it for foundation. About 500 lbs. of the same wax was sent to M. H. Hunt, direct from the parties above mentioned, and whom we supposed to be reliable, *before* we suspected adulteration; but as he was on his guard he set it to one side, pending further investigation. Another lot was sent to W. A. Selser, of Philadelphia direct, on our order from the same parties; but it was found by him to be impure. Fortunately we had used but very little of this wax ourselves, and that little, fortunately, too, was mixed with a large lot of pure wax. Paraffine or mineral wax is a positive detriment in comb foundation, as we learned years ago. The bees will build it out beautifully, but it has a disagreeable fashion of melting down in the hive. Even foundation from pure beeswax does this bad enough at times, but nothing like the stuff made of paraffine. Mr. Selser is a little fearful that a good deal of the wax on the market is adulterated. That being the case, let foundation-makers be on

their guard. A large part of our wax comes in small lots from bee-keepers direct, and, of course, is all right.

Later.—Since writing the foregoing we have received a letter from Ch. Dadant & Son, from which we make the following extract:

We have received your sample beeswax, and must say that at first sight we should have been "taken in," for it smells and looks like pure beeswax. A careful test, however, by the alcohol and water test showed that it has a lighter specific gravity than average beeswax. We should like to ask you by what sort of analysis you found that it had been adulterated, and also who sold it to you. Such men should be spotted, so every one may beware of them.

We never buy beeswax that has been remelted, for the only time that we ever received such a lot we found it to be very largely adulterated—much more so, in fact, than the sample you sent us.

I will explain that we sent them a sample of the wax, stating that we had found it to be adulterated, and asked their opinion on it. The wax is so skillfully adulterated that very few experts would have doubted its purity, and it is not much wonder that we were "taken in."

We hardly like to give the name of the parties of whom we bought the wax yet, for it is not entirely clear that they were acting in bad faith. They declare that they bought the wax on sample, and sold some to us in the same way; but what we have been trying to find out of them is, who it is they bought of that is adulterating wax so skillfully that even experts are misled. It is presumable that the adulterators will be flooding the markets with these goods unless restrained. All foundation-makers should be on their guard at all events.

The chemist, under the instruction of Mr. Selser, our agent at Philadelphia, and without our knowledge, also analyzed a sample of our foundation—some Selser had left on hand. It was taken from our last year's stock, and, of course, was like all the rest we sent out last year. Well, now, this showed that it varied from 94 to 98 per cent pure. In view of the fact that pure beeswax will contain more or less impurity in the way of dirt, etc., and the further fact that chemical analysis can not be expected to reach down to fine notches, it is very gratifying indeed. Mr. Selser, in commenting on the above analysis, writes: "My estimation of the A. I. Root Co. is higher than ever; for I am satisfied that, if it is possible for you to get pure beeswax you intend to do so."

We are not afraid at any time to have our wax analyzed, and I feel very sure that the Dadants and Mr. Hunt have the same feeling regarding their own wax.

WHAT WE DO AND DO NOT KNOW ABOUT BEE-PARALYSIS.

It occurs to me that the subject of bee-paralysis has been discussed in our own columns as far as it ought to be for the present. Further experiments should be made by some of the ex-

periment stations, by some professor with plenty of money and a good microscope at his disposal. There are a few things that we know about bee-paralysis. We all agree, perhaps, that it kills bees; is virulent in some localities, especially hot climates, and harmless in others, or in colder climates; appears and disappears as it pleases; bees swell up, look greasy, crawl out at the entrance, show a trembling, and die in the grass; the discharge is thin and watery.

Now for the points upon which there is not an entire harmony of opinion: Is it contagious? is it hereditary? is it caused by bad food? can it be cured by the removal of the queen? by administering salted water? can it be cured at all by any known remedy? Answering the two first questions, I am satisfied in my own mind that it is both hereditary and contagious. Certainly, if we accept that view of it, it will be safer for all parties concerned.

It seems to me that our present knowledge of the disease is not sufficient for us to answer the other questions, and for that reason it is just as well to let the subject drop in our columns, for a time, at least, until further developments shall have taken place. While some are doubtless interested in the discussion of the question, a great majority, perhaps, would prefer to read something else.

WHAT HAVE WE LEARNED FROM THE DISCUSSION OF LARGE VERSUS SMALL HIVES?

If our readers are getting tired of this hive discussion, large versus small brood-nests, I wish they would send in their postals, letting us know. On the other hand, if you feel that you are benefited, and would like to see the subject discussed further, let us know that also. GLEANINGS is published to please its *readers* and not its editors or its special correspondents.

Let us briefly recapitulate some things we have learned in the hive discussion up to the present time. 1. There are more bee-keepers using large brood-nests than we were aware of. 2. Many more favor ten-frame hives in preference to the eight-frame than we supposed, although, if we could count the hands of those using the eight-frame hives and those using the ten-frame, I think we should probably find three of the former to one of the latter. 3. It seems probable to me, at least, that some are using too small brood-nests, say of eight-frame size, when they might possibly get better results with ten and twelve frame sizes. 4. In colder climates, especially where there is one main honey-flow in June and July, with very little fall-flow, the eight-frame size seems to be used most. In warmer localities, in many portions in the South, in Cuba, where the seasons are prolonged, and where there are months when the bees can gather honey, instead of weeks, as it is with us up here in the North, a large brood-nest of ten, twelve, and sixteen frame capacity seems to have the preference.

5. Instead of bee-keepers running from ten down to eight, as formerly, the tendency now seems to be from the small size to the large. 6. The double eight-frame hive of 16 frames is too large since 12 frames seem to afford the maximum capacity for most localities. 7. Supply-dealers (pity the poor fellows) will probably do a lot of growling, because it will be a nuisance to keep so many *sizes* of hives in stock, (to say nothing of styles), each size necessitating special covers, special supers, special bottom-bars, and special honey-boards. How nice it would be, dear brother supply-dealers (let us draw nigh and weep) if every bee-keeper could use one size of hive, one kind of frame, one kind of every thing. But, no. There are too many notions that are at variance—too many localities with different resources; too many things in general, to make us all think and believe alike.

THAT BICYCLE-RIDE FROM TOLEDO TO MEDINA
—HOW IT WAS DONE.

THE following is an editorial that appeared in the *American Bee-keeper* and will explain itself:

When we read of the long runs made by the Roots, A. I. and Ernest, on their wheels we almost turn green with envy. Such muscled, such endurance, are almost phenomenal—at least, so it seems to the writer when he reads in January 15th GLEANINGS where Ernest scored 109 miles in 9 hours, and the writer is a "century rider" too—in fact, the captain of a "century club;" but he doesn't take 109-mile spins in 9 hours for fun *very often*. Say, Ernest, did you measure that run with a cyclometer, or trust to the word of a "native"? or did you have a 30-inch cyclometer on a 28-inch wheel? Honest, now.

I did not suppose that I had made an extraordinary ride, or I would have mentioned some of the circumstances under which it was made. The lowest road record for 100 miles is something over five hours, I believe; and for the track for the same distance, considerably lower than that. It is, if I am not mistaken, quite a common thing for good average riders to make a century on good roads in eight hours, and yet my time was a trifle over this.

Bro. Merrill lives in quite a hilly State, and writes from that standpoint. The road from here to Toledo is practically a dead level, for it is not a great way, as you will see by looking at the map, from Lake Erie. There are but few hills, and they do not amount to much. Besides, about 30 miles of the road is macadamized; and along the whole distance the road is kept in fairly good order. Now, then, if Bro. Merrill will turn to a good reliable map of Ohio, he will find that a *direct bee-line* from West Toledo to Medina is about 93 miles—one map making it 91 and another 96. But it was impossible to take a road as direct as that. My route was through Genoa, Fremont, Clyde, Bellevue, Wellington, to Medina. Striking a bee-line from Toledo to Monroeville, and from Monroeville

to Medina, the distance measured by the map before me—not a railroad map, but one of Rand & McNally's—makes a total distance of 100 miles. But if you will trace the different towns that I went through, you will see that I had to vary from these two lines quite a little. And still more: There are quite a number of right angles that I had to make—due east and then due south, that, of course, would not show on an ordinary map. You will see, therefore, that the distance, 110 miles, is not far from right. But I did not get those figures from the map, but from the guide-boards, and we have them in Ohio at every corner. These made the distance a trifle over 110 miles. As to time, I carried a watch with me the whole distance, that never failed me, and the time according to it was 9 hours, not including stops for three meals of about one-half hour each. I have been over a large part of this road a good many times, and I do not think I have made any mistake. Indeed, I have made a far better record than that on a part of the route, but I will not tell it here for fear you will call it a fish-story.

At the age of 12 years I began riding the old-fashioned velocipede—a front driver. Later on, I rode the "good old ordinary;" and when the day of the safety came, like the rest I rode that. As a natural consequence, my muscles have had a better opportunity for development than those of most riders.

Now, I do not suppose I should be able to keep up with Bro. Merrill and his century company on his rides over his roads. Indeed, while in Wisconsin I tried to make a century inside of ten hours, just as I had done a number of times on Ohio soil; but I found that 40 miles over the hills and over sand was all I wanted to make, and I was "awfully tired" at that.

In all my wanderings on the wheel over the country, I never find any roads that I like better than the hard clay roads within 100 miles of Medina. York State roads, while in many places hard, are too hilly. Wisconsin roads are good in some places, but they are very apt to be sandy or hilly. The Illinois roads are pretty good; but in the western part of the State they are bad. The Indiana roads are good, comparing favorably with those of Ohio.

THE BLIZZARD IN TEXAS.

In a private letter dated Feb. 20, Mr. F. A. Lockhart informs us that they have just passed through the worst blizzard that was ever experienced in that part of Texas—the southern part. The mercury ranged there from 2 to 16 above zero, between the 8th and 14th. Many birds perished in the storm. The unusual sight of snow six inches deep on the level was witnessed, and in places it was drifted ten feet. Mrs. Atchley carried her best breeding colonies into the house, and thus her loss will be light. It was part and parcel of a storm which will become historical.

THE OYSTER INDUSTRY ALONG THE COAST.

Oysters are very plentiful all along, and a description here of the way they are handled will perhaps answer for any, especially the way they are handled in small places.

A little building stands out in the river, on piles. A woman and her children seem to have charge. The boys go out in boats, and pull up the oysters with a pair of long-handled tongs, something like two steel garden-rakes riveted together, after the manner of a blacksmith's tongs. The rakes are spread open, dropped to the bottom of the river, and the handles pulled together as the oysters are lifted into the boat. The boys run the boat up to the side of the little building, and a smaller boy takes a hammer and breaks the cluster of shells apart. The mother then pries open the oyster, empties the contents into a large tin can; and a pretty little miss with her wheel (a regular two-wheeled bicycle) then takes the oysters all over town in a little tin rail. Like the ice manufactured here, they are gathered and carried around to customers as fast as wanted. The day's work consists in supplying the demand. Dr. Oren tells me oysters grow only where fresh and salt water mingle. Where streams of fresh water run into the ocean, oysters are found along the shores. They are good only in the winter time. They spawn along in the spring, the spawn floating on the water and catching fast to sand, stones, etc., as the tide comes in and goes out.

Oysters are large enough to eat when about one year old. If you want great big ones, however, you must wait until they are two years old or more. I have heard people say the oysters are finer up farther north; but I certainly never found any more agreeable to my taste than what we have here in Florida. I could not help being impressed with the fact that this wonderful—this *tremendous* supply of luscious and nourishing food—is a special providence, or, as I have loved to term it, only *another* one of God's gifts. The great mounds of empty shells seem to attest that oysters have been a favorite food of mankind away back in the earlier ages.

In many places along the seashore there is a hard sandy beach sloping gently toward the water, but otherwise as flat and level as a floor, and almost as hard. It seems almost incredible that the receding waves should leave the wet sand so compact that a carriage-wheel scarcely leaves an imprint. Yet such is true. Saturday, Jan. 26, I took my first extensive wheel-ride. I made the distance from Daytona to Ormond, 6 miles, in 25 minutes. Perhaps I have mentioned that, for a month or more, I have been suffering from a cough and frequent chills, and I had begun to be almost afraid that even Florida wasn't going to drive them away; but when I got to riding my wheel at a good speed, with my mouth wide open, taking in the salt sea air, it seemed as if the chills and bronchial trouble melted away like frost before the sun. When one undertakes to leave the wet sand and get up on main land he encounters dry sand that drifts and piles up exactly like snow in the North. The sand is so exceedingly white and snowlike that one almost unconsciously pulls up his coat collar as he attempts to wade through the drifts. Of course, no wheeling can be done through this shifting sand.

As I passed the long bridge at Daytona I noticed a party of men and women fishing from the bridge. This is such a common thing that I paid no attention to it until somebody pulled out a two or three pound fish. I decided to slack up my wheel and look at the catch. Just then somebody spoke out, "Why, there's A. I. Root on his wheel, as true as I live."

I began wondering who in the world away down here in Florida should speak of me in that way. Just then the cashier of our bank in Medina, O., put out his hand, with a genial exclamation of surprise, for he was the man who had pulled out the big fish. Then another Medina man—in fact, a near neighbor of ours—came forward with his greeting, and I was surrounded by some of our own people.

I forgot to say that, on the seashore, there are many wonderful things. Beautiful shells of variety without end are brought up by almost every receding wave, and occasionally a jelly-fish as big as a tin milk-pan. Now, they call this a *fish*; but imagine a piece of the most transparent glass, the size of a common sauce-dish, and you have exactly one of the smaller jelly-fish. The only thing that makes it look like a plant or animal is that, on one side, there is a series of scallops as regular and perfect as ever seen in any glassware decorations. The animal can not have any organs of nutrition or digestion—at least, so it seems to me, for it is so transparent; yet the keenest eye can see nothing. Right here I am told that the above is not quite true, and a lady says they have sense enough and life enough to *sting*, and that she has been stung herself. On further questioning she says they do not sting unless you break them open. Then they exude an acrid juice. Perhaps some scientific reader can tell us more about this queer phenomenon. On further questioning, those who are acquainted with them say that, if you pick them up, they will pull all to pieces because they are made entirely of soft jelly.

Our next move brought us to the home of J. Y. Detwiler, who lives on the peninsula opposite New Smyrna. Friend Detwiler has a beautiful house, visible for a mile or more in different directions along the coast. As he has been for many years more or less of a bee-keeper, our bee-keeping friends will find his rooms to let quite convenient, both to the seashore and the pretty little town of New Smyrna. Sunday morning we found our way to the Congregational Sunday-school. I think friend Detwiler introduced me to the superintendent as something of a Sunday-school worker, and very soon I was called upon to speak to the school. At the intermission between Sunday-school and preaching service the pastor of the church, finding out who I was, insisted that I should occupy the pulpit in his place. He gave as a reason that quite a number of people were present that day from Hawks Park, the home of W. S. Hart, and that, by previous arrangement, he had agreed to let me talk to the bee-keepers and others who might be present. Here I was in a predicament. I had not thought of any thing of the kind; in fact, our Sunday-school quarterly had been left at some of our previous stopping-places so I had not even given my usual thought and preparation to the subject of the lesson. However, I hastily chose a text and spoke as well as I could. At the close of the meeting the good pastor announced that A. I. Root would speak again briefly at the Christian Endeavor meeting, Sunday evening. As the Endeavor meeting was at seven o'clock, and friend Detwiler lives more than a mile away across the water, we were obliged to go to the meeting in the evening after dark, in a sail-boat, as we had in the morning; and it is

this boat-ride after dark that I want to speak about especially.

The minute we touched the water, friend Detwiler shouted to me to see the phosphorescence. I had heard of such a thing before, but I confess I had never even faintly realized what it was to see a boat literally plowing through liquid fire, throwing up sprays and rolling tiny red-hot (apparently) globules over the water at every splash. When he took the oars it was really a splendid display of fire-works. I dipped my hand down in the water and tossed it about. We soon discovered that the display was much more vivid at some points than others. Friend Detwiler said he thought this was because some portions of the water were warmer than others. When we stepped from the boat to the shore I went to examining the phenomenon along the sandy beach, and exclaimed, "Why, look here! this phosphorescence is clear out of the water, and sparkling away up on the gravel."

He came to my side, but soon began to laugh. "Why, Mr. Root, you are so excited that you are walking right down into the *salt water*, and imagining you are on dry land."

Thus ended a very busy Sabbath day, and to myself, at least, a very happy one. Our readers will find my talk to the Sunday-school embodied, with a little alteration, in a Home Paper for this issue.

Monday morning we moved on to Hawks Park. Perhaps I should remark that I took a hasty ride on my wheel Saturday night down the beach from New Smyrna to Hawks Park, to let the bee-friends know I was in the neighborhood. While there I invited them to come up to New Smyrna to church; and this, perhaps, somewhat accounted for a part of the audience on Sunday. While the greater part of Florida can not be called the best ground for wheeling, I want to say there is nothing in the world, at least so far as I have found, any finer than the shell roads along the river in New Smyrna. I rather prefer it to the ocean beach, because it is just enough up and down, with nice little curves to vary the monotony. I had to hurry up some on account of the coming darkness on that Saturday night; and swinging around the curves and going up and down on that shell road with its wonderful tropical scenery and strange sights on every hand was one of the most inspiring and enjoyable rides I ever made anywhere. I had another one over the same route Monday morning, in going to Mr. W. S. Hart's. In passing friend Hart's orange-grove from the road, you get only a glimpse of some sort of building back through the thick growth of forest. But when you open the gate and go inside, there seems to be a pretty good building all unoccupied. A little beyond are the orange-groves. Each grove comprises, say, from one to two acres, and around each is a belt of unbroken forest to shield it from the frosts and cold winds. Each tree is a model of symmetry and vigorous growth, and nowhere in Florida have we seen oranges of such size and symmetrical shape, together with perfect color, as we found here. The secret of it is perfect cultivation of the soil, liberal use of commercial fertilizers such as are found to be best, with thorough spraying to get rid of rust and scab, or any thing that might mar the beauty of the fruit. Friend Hart has for years been prominent in the horticultural work of the State of Florida, and has, perhaps, as perfect knowledge on all matters pertaining to Florida fruit culture as any man in the State. Therefore it is no wonder that his fruit is second to none. In fact, he gets a fancy price for it, for none but fancy fruit goes out with his brand. His orange-packing house

is a model of neatness and convenience, embracing all of the most improved inventions up to the present day. He pays an extra price for better material for boxes than I have ever seen used for the purpose. In fact, when we visited the Congregational church on Sunday I was struck with the wonderful beauty of some panels selected from specimens of Florida pine. When I asked about it I was told the panels were selections from some of the finest boards used for the sides of orange-boxes. The hoops with which the boxes are bound are made by an invention of Mr. Hart's, from long slender stems of palmetto-leaves.

The process of gathering and packing is something like this: The fruit is carefully picked, using ladders and step-ladders for the highest branches. It is placed in a peculiar basket something like the German tub hung over the shoulders, as illustrated in GLEANINGS for 1894, p. 202. The pickers take every thing—good, bad, and indifferent. Then the fruit is poured out into a peculiar orange-box, made so one will pile up over another and keep its place securely, yet with the sides so low that the pickers can not heap the oranges so the box above will mash them. Not an orange is bruised or mashed during the whole process. They are drawn to the packing-house in a wagon, and emptied into a large slatted-bottom tray or vat. This tray swings on pivots so the oranges may be made to roll either side of it. The first-class, gilt-edged fruit, is selected and thrown into a hopper. This hopper, by an ingenious arrangement, sorts the fruit, placing each size by itself, sorting them from 96 to the box down to 250. Each size is then picked up, papered, and packed. Each paper is stamped with friend Hart's brand, and a pretty show-card is put on top. Some scalloped shelf-paper is daintily placed around the edge; then the smooth veneer covers are put in place.

Now, the old-time way is for the packer to put his knee on the cover, bringing it into place, bruising and mashing some of the fruit. Not so here. A pretty piece of mechanism brings the cover gently against the fruit, forcing it down hardest right where it is to be nailed. In fact, the fruit is handled almost like eggs, and the boxes, too, are handled as if the contents were eggs, as far as possible, until they are in the hands of the consumer. Mr. Hart's trade is principally with a class of people who want the prettiest oranges to be had, even if they do have to pay a little more for them. I have taken pains to give these full details, because it is exactly what I find whenever I visit a fruit-grower or even a farmer, who gets gilt-edge prices for his products. A handsome package certainly goes a long way toward getting good prices. Orange-packing establishments, bee-keepers' apiaries, and other like places that are used at only certain periods of the year, are very likely to be found untidy, full of cobwebs, etc. Now, friend Hart may have done some clearing up because he expected me to come and may be make comments in regard to his arrangements. But even if he did, he ought to have much credit for succeeding so well. His whole packing-house and much of its complicated machinery is made of resinous Southern pine; but every piece of wood about the whole place seemed to be not only planed smooth, but sandpapered until every thing looked like glossy hard-wood finish in a nice dwelling-house. The multitude of little conveniences and inventions in the way of short cuts makes one readily believe he has studied to simplify the details, perhaps day and night, for years.

While in the orange-packing house we noticed the following courteous hint to loungers,

and it hits the point so exactly that we copy it, thinking it may be of use to others who have similar places of business:

"Callers are welcome, but I trust they will bear in mind this is no place for long stories, loafing, or gossip."

His honey-house and apiary are a good deal after the same plan. The frames of honey are wheeled up to the upper story of the honey-house, in a cart made for the purpose. After the honey is thrown out it runs by gravity into a sun evaporator, the honey flowing around partitions so as to go slowly zigzag over a large extent of surface, glass sashes being placed over it during the evaporation. Of course, it is placed where it will get the full benefit of the direct rays of the sun. From the evaporator it goes into a large storage-tank from which it can be readily drawn into barrels. Something like sixty barrels, containing twelve or fifteen tons of honey, were stored in the lower story, or honey-cellar, during our visit.

The above is just about half of the whole crop of honey.

As there has been some bungling in the attempt to give the exact amount of honey stored by a single colony placed on scales during the season of 1894, we give the following figures, taken from Mr. Hart's memorandum-book:

May 14.....	57	lbs.	June 16.....	44	lbs.
May 22.....	30	"	June 25.....	50	"
May 27.....	12	"	June 27.....	15	"
May 28.....	42	"	July 6.....	56	"
June 2.....	51½	"	July 16.....	53¼	"
June 11.....	46	"	July 26.....	48¼	"
June 12.....	15	"	Aug. 6.....	14	"
Total.....				554¼	"

By the way, I want to say here that friend Detwiler wants all bee-keepers to test dipping-boards made of Spanish cedar. It can be purchased in our large cities; but you can test it on a small scale by using the cover of a cigar-box. His boards are always made of Spanish cedar. He says it does better work, and lasts longer, than any other kind of wood to be found in the world.

It is quite interesting to go over friend Hart's grounds and around his house, and see the great variety of fruits that may be grown with more or less success in Florida. Here for the first time we saw the wonderful scuppernong grapevine. A single vine, if given trellis enough, with a little training will cover almost a quarter of an acre; and this one vine will often yield hundreds of pounds of fruit.

Mulberries are largely raised in the South, and somebody suggests they can be grown so cheaply that they are valuable for the chickens, keeping them from having a desire to meddle with other more valuable fruits. Guavas also will yield fruit almost every month of the year; and, judging from specimens of canned ones, as large as apples, furnished us at Dr. Oren's, we regard them as a most pleasant and agreeable substitute for apples. Brother Hart says they are the poor man's apples in the South. The bushes grow with wonderful luxuriance on almost any soil, and without any care; in fact, the dryer and poorer and more sandy the soil, the better the guava seems to flourish. The fruit is even now hanging on the bushes; but both bushes and fruit too were used up by the frost. We are told the bushes are killed clear down to the ground; but no one seems to think it matters very much, for they will be up and in full bearing again in an incredibly short space of time. Cuttings for figs are sometimes planted in the spring, and yield a crop of ripe fruit before another spring.

Dr. Hawks, who gave Hawks Park its name, paid us a visit during the evening. He has written a book entitled "The East Coast of Florida," and it contains matters of much in-

terest pertaining to this coast of Florida. The book is the result of his own travels and investigations. He paid me a high compliment in something like the following words: "Mr. Root, you are not aware, perhaps, of the extent of the great industry you are largely instrumental in starting up all over the world, especially through Florida. Your enthusiasm and zeal did much toward developing bee culture, and in advance of what it would have been otherwise, and your A B C book is still doing its work of making the desert bloom and bear tons upon tons of a delicious food product." And this reminds me that friend Hart said I must call upon a young man who is just commencing in the bee-business. We found him poring over the pages of the A B C. His bees had got to robbing, and he was in trouble to know how to stop them. I told him to come along with us, and either friend Hart or myself would fix the robbing business in short meter. I felt sure we could, because the bees were gathering considerable pollen and some honey. Well, several colonies that he supposed were robbing were, in my opinion, only having a play spell. There was robbing, however, at one stand. This stand had the nameless bee-disease, or bee-paralysis, when he purchased it. Somebody had said through GLEANINGS that feeding was a good thing. Now, though the bees had an abundance of sealed stores he put in an additional story and set in a dish of honey, and this dish of honey caused the robbing. To stop it he had kept the bees shut up for three days, so they would not know where their old home was. We let them out, and in ten or fifteen minutes they organized a guard around the entrance, dragged out their dead, and took care of themselves. Friend Hart says he has never had this disease kill a colony in his own apiary. Sometimes it disappears of its own accord, and it almost always does after giving the bees a new queen. By the way, I am told by all the bee-keepers I have met that foul brood has never yet been seen in Florida. If bee-keepers could unite and stamp it out at the outset, if it ever does appear, it will be worth thousands and thousands of dollars to the State.

Our next visit was at E. A. Marsh's. To reach the place I made a trip of eight miles on the wheel, and the most of it through the soft sand. For the first time since my severe cold and hoarseness, contracted about Christmas time, I rode in my shirtsleeves, with vest unbuttoned, and bareheaded. After my trip, while wet with perspiration, I took a bath in the salt water of the Hillsboro River, and did not take a particle of cold; in fact, I knew I shouldn't. The thermometer was up to between 80 and 90°.

Friend Marsh's people have come all the way from Massachusetts, and have lived here about nine years. They put up a temporary dwelling for camping out, and they laughingly said they were "camping out" still, with no desire to go back up North. In one respect, at least, they are a remarkable family. For instance, while there an intelligent, beautiful-looking horse by some hook or crook got into the garden stuff down in the hammock. Friend Marsh stood in the door and called to it away across the lots. The horse came up at once, and part of the way at a very brisk gallop. Now, he did not come because he expected to be fed, for, as soon as the gate was opened, he went straight to the stable where he belonged. Mrs. Marsh said the pigs and chickens would do the same; and by way of a crowning exhibition of what intelligent training will do for the animal kingdom, her daughter, with a bit of cake in her fingers, called some beautifully plumaged blue-jays out of a neighboring tree. They alighted

on her hand, and ate the cake. Afterward Constance did the same thing, thus proving that it was not because it was some one they had become acquainted with. We were told they did this when a woman offered them food, but they hadn't the same faith in *man*kind.

I should right here describe friend Marsh's gardening, but a more extended description of the same thing will be found in our visit to friend Fröscher's.

For flesh and blood hath not revealed it unto thee, but my Father which is in heaven.—MATT. 16: 17.

I have mentioned elsewhere (see page 186) the Sunday-school at New Smyrna. That Sunday morning I discovered our quarterly had been mislaid or lost, and we were too far from any one who had the lesson to find out exactly where it was, before going to the church. As soon as I took my seat in the class I began looking over the lesson hastily; but before I had hardly gotten a glimpse of it the superintendent of the school asked me to give them a little talk in regard to the lesson just before closing. For a time it really seemed as if I couldn't collect my thoughts or find a single point in the whole lesson on which to base any remarks. I have never been in the habit of refusing any such request; and, in fact, quite a number of bee-keeping friends were present, and it would look a little singular for *A. I. Root* to refuse to speak just a few words to them. I commenced praying to myself that God would give me of his Holy Spirit that I might not disappoint the friends who were looking to me, perhaps, for a little portion of the "bread of life," and that I might have wise counsel and encouragement for any who might be fainting by the wayside. For a time it seemed almost as if I should be obliged to ask to be excused. Satan suggested that it was out of my line; that I was out of health; that I was too hoarse to talk, any way, etc. But I held fast to the Bible promises. I had been through similar trials before, and had faith to believe that my petition for help would not remain unanswered. I thought of the text, "If ye, then, being evil, know how to give good gifts unto your children, how much more shall your heavenly Father give the Holy Spirit to them that ask him?"

Just before the lesson closed, and almost as the superintendent began to introduce me, my mind began to center upon the text at the head of this talk, and for the first time in my life the latter part of the 17th verse had a new—a wonderfully new—meaning. All at once I began to comprehend that the plainest evidence any mortal ever had of the truths of the Christian religion was the evidence of the Holy Spirit, the words that God the Father speaks to the heart of each child of his. And this was my message to the people, most of whom I had never seen until that morning. As I stood before them I told them of the Sunday-school away off in Ohio, of the class of boys that gathered every Sunday, to be taught by me. I told them of the old mother who also was always present at that Sunday-school, and of an experience in her life she had told me of again and again. That experience was something like this:

She united with the church when only twelve or fourteen years old; but as there was a good deal of gaiety, going to parties, etc., shortly after, her religion began to seem to her a rath-

er secondary matter, and she drifted away at last, to a certain extent, as many an older Christian has often done. She was at that age undecided as to what she ought to do about going to dances. Her father rather preferred to have her go, and his influence was of a somewhat worldly character. She finally felt so uneasy and unsatisfied that she prayed very earnestly that God's Holy Spirit might guide and direct her, and tell her what she ought to do. She also prayed most earnestly for a plain and clear evidence that she was a child of God, and that the teachings of her Bible were *true*. You will please consider that she was getting considerably under the influence of those who led into skepticism rather than toward a devoted Christian life. She says that her prayer was at once and with *wonderful distinctness* answered. The bright peace and joy that came with the answer was so clear that never *once since*, in a busy life of almost 70 years, has her mind so much as *wavered*. That answer was the secret of the bright clear faith that has shown from her face and every act during all her life. I have never, since I can remember, seen my mother lose her faith. I have seen her on her knees in earnest prayer, and I have heard her voice in prayer for myself and every other member of a family of seven children. The fact that I stand here to-day with a like faith, bright and clear, I owe to that mother's faith and teachings and prayer more than to any thing else in this world.

Jesus tells us, in the words of our text, that flesh and blood did not reveal unto Peter that Christ was the Son of the living God. It wasn't the testimony of friends; it wasn't the teachings of the pastor; but it was God's Holy Spirit, the Father in heaven, who revealed this wonderful truth to Peter.

And now, dear friends, for the personal application. If there is any one whose eyes are resting on these words, and who doubts the divinity of Christ, who feels undecided in regard to the claims of Christianity, the very best evidence that can be given in the *whole wide universe* is the testimony spoken, perhaps not in words, but in some way still plainer—the testimony of the Holy Spirit. Go to God in prayer; go to Him who fashioned us after his own image—the Father who created us and brought us into the world—he who is the beginning and end of all things, and ask *him* to make it plain to you what you ought to do. He will guide you and direct you. He will tell you what no other being can tell, and he will tell you the *truth*. The evidence that every Christian may have, if he has not had it already—the evidence straight from the Holy Spirit to the heart of the inquirer—is the best evidence we can possibly have.

My experience was much like my mother's. I shall never forget the time when I knelt alone by myself and uttered my first prayer—at least, the first prayer since I had arrived at the age of manhood. It was a simple, honest petition for help and guidance. Why, dear friends, I was in so much doubt and uncertainty—in so much *distress* because I was tossed about in the wild sea of doubt—that my first words were, "O God, if there be a God, listen and hear the petitions of thy poor unworthy child." I don't remember the rest of the prayer uttered in the darkness of the night, alone by myself; but I do remember the faith and peace and joy that came upon me all at once—a faith that has never deserted me—no, not for one brief instant. I have been through trial and suffering; I have almost lost consciousness in the delirium of fever; I have been sorely tempted by the evil one at such times of temptation; I have again and again prayed for help, even as a child in

distress calls to a parent; and this same Holy Spirit has again and again spoken peace to my soul.

Another office of the Holy Spirit is to rebuke and reprove and convict. One who prays for the influences of the Holy Spirit must expect to have his shortcomings made plainer to him than they ever were before. He must expect to see sinfulness in the light that God sees it. Sometimes we persist in our stubborn ways until our neighbors and best friends are obliged to remonstrate with us. These friends feel pained at our course, and naturally dread the disagreeable task when it must be done. Very well; if you pray that *God's Holy Spirit* may guide you, it will begin, in time, to tell you of your faults; in other words, the twinges of conscience will come oftener and plainer when you do wrong than ever before.

I may never see you again, friends. These words may be the only ones you will ever hear from my lips; but I do not know any more valuable message I can give you than to tell you to pray often for the guidance of the Holy Spirit, especially when you are in doubt. Then is the time to ask the God who made you, of the truth of the Christian religion. If any one here is ever tempted to doubt that Christ is the Son of God, let him go to the Father and he shall surely have an answer. Of course, I am presuming that this prayer is an honest one; that the one who utters it is ready and willing to do God's will; that he is ready to give up all and every thing for the truth when it shall be made known to him. Do you doubt God's willingness and readiness to give personal assurance to every child of humanity? Read again the words I have once before quoted:

If ye then, being evil, know how to give good gifts unto your children, how much more shall your heavenly Father give the Holy Spirit to them that ask him?—LUKE 11: 13.

Peach-trees! By mail, 10 for 60 cts.; by freight or express, \$4 per 100. Crosby, Elberta, Stump, and other best varieties.

Japan Plums. Abundance, Burbank, and Satsuma; by mail, 5 for 60 cts.; by freight or express, \$10 per 100. Cedar Grove Farm.

JOHN CADWALLADER, Proprietor,
North Madison, Indiana.

Talmage, Otoe Co., Neb., Dec. 8, 1894.

John Cadwallader.—Dear Sir:—I received your trees Nov. 22 in good order, well packed, and thrifty-looking trees. Thank you for the Satsuma.

Yours respectfully, JAS. RITTER.

Here is a report of one order sent by mail April 7, 1894. It embraced 10 peach trees (5 sorts) and two Abundance plum, the whole cost 90c. Remember I pay the postage and send 10 peach trees for 60c.

Mexico, Mo., Jan. 7, 1895.

John Cadwallader, Dear Sir:—The trees received of you last spring all lived and did well.

I want a few trees next spring. B. BALDWIN.

The New Craig Seedling Potato.

For full description of this Potato, see page 959 of this journal for Dec. 15, 1894. Prices: 1 lb. by mail, postpaid, 25 cts.; ½ peck, by freight or express, \$1.00; peck, \$1.75; ½ bushel, \$3.00; bushel, \$5.00; barrel of 11 pecks, \$12.50. The above prices will hold good as long as our stock lasts. All orders by mail will be filled as soon as received. Orders by express will be shipped at once unless ordered otherwise. All orders for potatoes by freight will be filled April 1, or soon after that time, unless directions are given to ship at an earlier date. In this latter case I do not assume responsibility for loss in freezing; but where it is desirable to ship earlier, and customers have bad luck, I expect to help them out so far as I can consistently. In regard to my responsibility I would refer you to A. I. Root. In fact, where it is more convenient you can order potatoes of the A. I. Root Co., instead of sending your orders to me.

GEO. E. CRAIG, Zimmer, Franklin Co., O.

Raspberry Plants For Sale.

Gregg for late; Hilborn for medium; Palmer for early.

These are standard varieties, giving almost universal satisfaction.

They are the kinds to plant for berries.

Price \$1.00 per hundred; \$7.00 per thousand, F. O. B. at Lodi.

W. R. GRANNIS, Lodi, Ohio.

B 4 U Buy Seeds or Plants,

Send for my
Annual Catalog.

It is neatly gotten up; no old stereotyped matter about it; nothing sensational. The Best Varieties truthfully described and honestly priced. A. I. Root says, "I believe I have read every catalog you have put out clear through, and I wish all seedsmen would tell us their experience with different varieties as frankly as you do." True Prizetaker onion seed and plants a specialty. Vegetable and small-fruit plants of all kinds, trees, and supplies for gardeners. Send for free catalog at once, or send 10c for catalog, a pkt. of a new smooth very early tomato, a pkt. of the best new lettuce, a pkt. of true Prizetaker onion, and a pkt. of choice flower seeds, all for 10 cents.

In responding to this advertisement mention GLEANINGS.

CARLOAD SHIPMENTS.

We have shipped the past month a carload of hives and supplies to W. O. Victor, Wharton, Tex. There were 500 hives in the car, all ten-frame, and mostly for extracted honey, which shows the kind of hives preferred in that section. Mr. Victor has 450 colonies of bees, and produced 45,000 lbs. of honey the past season. Bee-keepers in that section may supply themselves from his stock. We have also shipped a carload of hives and supplies to O. P. Hyde, Lampasas, Tex. These are almost all eight-frame hives, and for comb honey. But then the two points, although in the same State, are a good way apart. Mr. Hyde is also prepared to furnish the bee-keepers of Northwest Central Texas.

As we go to press we are making up a car for St. Paul, Minn., and another for San Mateo, Fla.

HONEY MARKET.

The crop of honey the past season must have been more abundant in many quarters than the reports indicated, or else the people are not eating as much as they did in better times. No doubt both are true to some extent. At any rate, there seems to be a plentiful supply, and very low prices are ruling. We are prepared to furnish, to those who need it, either comb or extracted of choice quality—comb, in 1-lb. sections, at 15c per lb.; large lots at a less price, which we will quote to those interested. Extracted, in 60-lb. cans, two in a case, at 8½c; two-case lots or over, 8c. We have choice white alfalfa and clover and basswood at these prices; also some very good honey, not quite equal to above, at a cent a pound less. Samples submitted to those interested.

SECOND HAND FOUNDATION-MILLS.

Since our last report five more of the second-hand mills have been sold. One more ten-inch has come in since, and one or two more are expected. The stock at present stands as follows:

Six-inch hex., No. 1461. Price \$10.00. This is in good condition, and just right for thin surplus foundation.

Six-inch hex., No. 1631. Price \$10.00. In good condition, and will make thin surplus foundation 10 ft. to lb.

Six-inch hex., No. 1565. Price \$12.00. This is in good condition, with very light wall, and will make extra thin foundation about 11 ft. to lb.

Six-inch hex., No. 1669. Price \$10.00. This has made a good many hundred pounds of thin surplus foundation in our wax-room, and will still do good work; has a few slight blemishes which are no detriment practically, but hardly suitable for the high standard of excellence attained by our foundation.

Ten-inch round-cell, No. J. J. old-style frame. Price \$10.00. Has been used but little, and is in good condition. It is well worth the price to any one wanting to make medium foundation for their own use.

Samples from any of above mills sent on application to those interested.

LEININGER BROS., FT. JENNINGS, O.

W. O. Victor, of Wharton, Tex., took

45,000 Lbs. of Honey in 1894.

He offers Italian Queens—good, old-style honey-queens—untested, first order, to any address, at 50c each. Also bees in any quantity; 450 colonies to draw from. Root's goods constantly in stock. Prices to suit the times. Buy near home, and save freight.

S. J. ENGLISH, Englishville, Ga., will deliver f. o. b. Andersonville, Ga., 30 COLONIES HYBRID AND ITALIAN BEES, ON L. FRAMES, For \$100.00.

KIND WORDS FROM OUR CUSTOMERS.

The wire netting was received in good order. I am well pleased with it. I don't see how you can sell it so cheap—just half what it would cost at my hardware store, after paying the freight. Prosperity to the Root Co. is the wish of your friend.

Hampton, Ky., Jan. 28.

G. W. DULEY.

THOSE NEW ROOT POLISHED SECTIONS.

I am much pleased with the 8000 1-lb. sections you sent me. I have already set up 5000. They hold out all right, besides the breakage. They are very nice.

Spragueville, N. Y., Jan. 30.

WM. HULL.

OUR WORK CAN NOT BE BEAT.

The goods were received, and the cases and frames are all nailed up. They were all perfect, and went together without any trouble. Your work can not be beat. Thanks for the extras.

Manchester, N. Y., Feb. 2.

EZRA G. SMITH.

THE CRANE SMOKER.

I bought a Crane smoker of you last spring, and like it very much. I have used other smokers, but find it far superior to any of them. The blast is as strong now as when I got it, and it saw as much service as a smoker generally does in a season.

Calamine, Wis., Jan. 6.

F. L. MURRAY.

ARTICLE MORE THAN FAIR.

I have read your article in GLEANINGS (on the dovetailed corner), and I thank you very much for the kindly spirit in which you have written. Surely your article is more than fair, and I said to Mrs. Abbott that I had not a word of fault to find. There is one thing, however, that I desire to say, so I may not appear to condemn a thing without seeing it. I have one of your hives which came direct to me from you, and I have had a sample once before. They are made the best of any of the kind I have seen.

St. Joseph, Mo.

E. T. ABBOTT.

QUEENS ALIVE TO AUSTRALIA BY MAIL.

Your postal card and queen-cage arrived here Jan. 16. All the bees were dead except two and the queen. I introduced her into queenless nuclei the same day, and she is apparently doing nicely.

Tryphena, New Zealand, Jan. 22. JOHN BLAIR.

The queen you sent me arrived in splendid condition Jan. 8, 1895; in fact, she looks as though she were just caged. There were 7 bees dead, all the way from a dry-looking bee to one just dead. I have put her in the hive, under wire netting. Although liberated by the bees, on looking through the hive I could not sight her. I am afraid I have made a mistake in putting her into a colony which was preparing to swarm, first taking five frames of bees and brood and queen to start another hive.

JAMES H. COLMER.

Woolbrook, New England, N. S. W., Aus., Jan. 14.

Dear Friend Root:—I have much pleasure in informing you of the arrival of the queens Jan. 10. The select tested queen was dead, and all the bees except one; but the other lot was in splendid condition—only 6 bees dead. I consider the double box a great improvement, and very suitable for this country; and they had abundance of food that would last them as long again, and it was in splendid condition. I don't think the tested queen could have been long dead, because she looked quite fresh. I am also sending you our local paper, where you will see the account of their arrival. I have to thank you very kindly for your promptness in forwarding me the bees. I am highly pleased with the one that landed alive.

Alex. BAIN.

Asylum, Toowoomba, Queensland, Aus., Jan. 17.

I am glad to report that the Italian queen sent by you in September last has arrived alive, and has been introduced safely—only one worker was alive when she arrived. I have not seen the queen yet, as I was away from home on a visit to Sydney, and have only just come home again. I intend to raise some young queens from her at once. Please accept thanks for sending the queen. She arrived here October 20.

Huonville, Tasmania, Nov. 8.

E. LINNELL.

D. G. TUTT GROCER CO.,
Mar. 8. St. Louis, Mo.

CLEVELAND.—*Honey.*—The demand for white comb honey is somewhat slow. No. 1 1-lb. sections are selling at 13@14; No. 2, 11@12. No. 1 water-white extracted, 6@8. Beeswax, 26@28.
WILLIAMS BROS.,
Mar. 7. 80 & 82 Broadway, Cleveland, O.

BOSTON.—*Honey.*—We quote you our market on comb honey at 13@14c. with supply light, and fair demand. Extracted, 5@6.
E. E. BLAKE & Co.,
Mar. 9. Boston, Mass.

BUFFALO.—*Honey.*—Honey market is extremely quiet; still, our stock has moved off quite well considering the times, and indications are that we shall be able to clean it up. Sales to-day of fancy, 14@16; storage, 10@12. Off grades and irregular quality of honey are moving slowly at prices ranging from 8@10c; buckwheat is also extremely dull at 7@8. Extracted honey finds very little sale here. Beeswax, 25@30.
BATTERSON & Co.,
Mar. 7. Buffalo, N. Y.

PHILADELPHIA.—*Honey.*—Comb honey in better demand at 12@13 for best white. Extracted in fair demand at 5@6. Strictly white clover at 8@9.
WM. A. SELSER,
Mar. 8. 10 Vine St., Philadelphia, Pa.

DETROIT.—*Honey.*—Best white comb honey is selling in a small way at 15c; other grades, 11@13. Extracted, 6@7. Beeswax firm at 28@30.
M. H. HUNT,
Mar. 8. Bell Branch, Mich.

CHICAGO.—*Honey.*—During the past two weeks a good movement has been felt in the market. Sales have been of small lots, or quantities, each time, but sufficiently frequent in occurrence to make the aggregate sales of some moment. White comb of the best grades, 14c; travel-stained or off in color, 13@13½; yellow comb, 10@11; dark, 7@9. Extracted, 5½@7, according to flavor and package—60-lb. cans of white bring highest price. Beeswax, 23@30.
R. A. BURNETT & Co.,
Mar. 7. 163 So. Water St., Chicago, Ill.

SAN FRANCISCO.—*Honey.*—The demand for both comb and extracted honey is rather light, and supplies are ample to meet all local demand. We quote to-day: White extracted, 8½@9; light amber, 5½@6½; amber and candied, 8@9. Comb honey, choice white, 9½@10; amber, 7@8. Beeswax, 26@27.
SCHACHT, LEMCKE & STEINER,
Feb. 25. San Francisco, Cal.

DENVER.—*Honey.*—There seems to be an improvement in our market; still, the prices remain about the same. No. 1 comb, in 1-lb. sections, 11@12; No. 2, 9@10. Extracted, No. 1 white, in 60-lb. cans (2 in a box), 6@7. We could handle to advantage a quantity of No. 1 comb honey; also pure beeswax at 22@25.
R. K. & J. C. FRISBEE,
Mar. 9. Denver, Col.

ALBANY.—*Honey.*—It is surprising where all the comb honey comes from. We supposed it was all in market, but we have had a large number of consignments, for this season of the year, during the past month, and there is also a very good demand. Clover sells at 11@13; buckwheat and mixed, 8@10. Extracted scarce, and sells at 5@7.
CHAS. McCULLOCH & Co.,
Mar. 8. Albany, N. Y.

SPRINGFIELD.—*Honey.*—Our market is very slow. Buckwheat, 10; white-clover, 13@14.

PERKINS & HATCH,
Mar. 9. Springfield, Mass.

CHICAGO.—*Honey.*—We report our market well cleaned up on fancy white comb honey in 1-lb. sections. A neat package and a fancy article would sell quickly at 14c. No. 2 comb, or dark, would not sell at over 10@11. We report better inquiry for extracted, at 5@7, depending on quality. Beeswax selling at 30c.
S. T. FISH & Co.,
Mar. 8. 189 South Water St., Chicago, Ill.

KANSAS CITY.—*Honey.*—The demand is only fair for both comb and extracted honey. We quote No. 1 white 1-lb. comb, 14@15; No. 2, 12@13; No. 1 amber, 13; No. 2, 10@11. Extracted, 4½@6. Beeswax, 22@25.
C. C. CLEMENS & Co.,
Mar. 8. Kansas City, Mo.

CINCINNATI.—*Honey.*—Demand is slow for extracted and comb honey, with a fair supply. We quote extracted honey at 4@7c per lb. on arrival. Comb honey at 14@16 in the jobbing way for best white. There is a good demand for beeswax at 25@28c per lb. for good to choice yellow.
CHAS. F. MUTH & SON,
Mar. 11. Cincinnati, O.

We offer California comb honey, 1-lb. sections, 36 sections to the case, at 10 and 11 cts. per lb., depending on quality. New York State 2-lb. sections, amber, 10c per lb.; white, 12c. We will either buy or sell extracted honey. Correspondence solicited.
S. T. FISH & Co., 189 So. Water St., Chicago, Ill.

Four barrels of basswood and fall honey for sale at 6¼c per lb., f. o. b. here.
CHAS. DADANT & SON, Hamilton, Ill.

Closing out balance of my fine extracted basswood honey at 7c f. o. b. Who is not supplied?
ELIAS FOX, Hillsboro, Wis.

ALFALFA HONEY, very white, thick, and rich. Two 60-lb. cans at 7c. Same, partly from clover (tinted), 6c. Samples, 8c.
OLIVER FOSTER, Las Animas, Col.

We yet have extracted alfalfa at \$7.80 per box of 120 lbs.
AIKIN BROS., Loveland, Colo.

BEESWAX WANTED.—Will pay 31½c cash for absolutely pure beeswax that will stand chemical test. Write me at once.
WM. A. SELSER, 10 Vine St., Philadelphia, Pa.

BUFFALO, N. Y. Unsurpassed Honey Market.
BATTERSON & CO. Responsible, Reliable,
Commission Merchants. 187fdb and Prompt.

For Sale for 1895 ITALIAN BEES AND QUEENS, AND ROYAL BEE KEEPERS' SUPPLIES.
Address OTTO KLEINOW, 122 Military Ave., Detroit, Mich.

25 Swarms of bees for sale, with or without hives, at Mountain View, near El Monte, Cal.
MRS. W. C. DAVIS, El Monte, Cal.

SEED POTATOES. Colvin's New Ideal. Best new Potato, E. Vorthier, Carman No. 1, Banner, 20 varieties; Dutton Flint Corn, Seed Oats, Small-Fruit Plants, etc., at Hard Times Prices. Price List free. Address **CEO. H. COLVIN, L. Box 6, Dalton, Pa.**

Jas. M. Smith, Perkiomenville, Pa., breeder of 16 leading varieties of Poultry. Eggs, \$1.00 per 15. Catalog free.

ITALIAN BEES Ready in May. Queens \$1.00. Bees by the pound, \$1.00. One-frame nucleus with queen, \$2.00; two frames, \$2.50. Also Barred Plymouth Rock eggs for setting, \$1.00 per 15.

CONVENTION NOTICES.

The Utah Bee-keepers' Association will hold its semi-annual meeting on Thursday, April 4, at 10 A.M., in the Fish Commissioner's rooms, in the new city and county building, Salt Lake City.

GEO. E. DUDLEY, Sec., Provo, Utah.

The next meeting of the Western Washington Bee-keepers' Association will be held on Monday, April 8th, in Horticultural Rooms, City Hall. Bee-keepers are invited.

G. D. LITTOOY, Sec., Tacoma, Wa.-h.

CIRCULARS RECEIVED.

Price lists of apianarian supplies in general have been received from the following parties:

Leahy Manufacturing Co., Higginsville, Mo.
Mrs. Fannie B. DeWitt, Sunny-ide, Md. Queens and bees.
G. B. Lewis Co., Watertown, Wis.
Emerson T. Abbott, St. Joseph, Mo.
L. J. Stringham, 105 Park Place, New York.
Charles F. Muth & Son, 976 Central Ave., Cincinnati, O.
W. H. Norton, Skowhegan, Me.
George W. Stephens, Denison, Ia. A new frame-spacer.
J. VanDeusen & Son, Sprout Brook, N. Y. Foundation.

Wants or Exchange Department.

Notices will be inserted under this head at one-half our usual rates. All advertisements intended for this department must not exceed five lines, and you must say what your adv't in this department, or we will not be responsible for errors. You can have the notice as many lines as you please, but all over five lines will cost you according to our regular rates. This department is intended only for bona fide exchanges. Exchanges for cash or for price lists, or notices of offering articles for sale, can not be inserted under this head. For such our regular rates of 20 cts. a line will be charged, and they will be put with the regular advertisements. We can not be responsible for dissatisfaction arising from these "swaps."

WANTED.—Old combs in frames. Describe, with price. W. L. COGGSHALL, West Groton, N. Y.

WANTED.—To exchange one colony of bees for M. B. turkeys. PHIL FISHER, Hannibal, O.

WANTED.—To exchange the only wax-extractor in the world that will extract all the wax from old combs rapidly by steam, also bee-smokers, for wax. C. G. FERRIS, South Columbia, Herk. Co., N. Y.

WANTED.—To exchange Universal wood-worker, one groover, one dovetailer, and one cutter-head table; also short jointer, all in good order. What have you to trade for one or all?
W. S. BELLOW, Ladora, Ia.

WANTED.—To correspond with parties wishing to sell or test my new hive. F. DANZENBAKER, 1110 New York Ave., Washington, D. C.
Reference, GLEANINGS.

WANTED.—25 to 100 hives of bees. Who can furnish them the cheapest? I will exchange, for bee-hive machinery, queens bred from a straight five-banded breeder valued at \$50, or from imported stock.
H. G. QUIRIN, Bellevue, Ohio.

WANTED.—To exchange 200 colonies of bees for anything useful on plantation.
ANTHONY OPP, Helena, Ark.

WANTED.—A quantity of drawn combs.
edit I J. STRINGHAM, 105 Park Place, N. Y.

WANTED.—To exchange Black Minorca eggs at 60c per 15 for a few untested queens.
H. BARBER, Adrian, Mich.

WANTED.—An improved Barnes foot-power saw, for lowest cash price.
J. EVERMAN, North Middletown, Ky.

WANTED.—To exchange raspberry and blackberry plants, \$6 per 1000, bees \$5, Japanese buckwheat, for beeswax. A. P. LAWRENCE, Hickory Corners, Mich.

WANTED.—Bees, bee-supplies, and poultry, in exchange for strong, well-rooted basswood-trees. This is the time to transplant.
W. R. LIGHTON, 601 N. Y. Life Bldg., Omaha, Neb.

WANTED.—To exchange yellow Italian queens the coming season, also the best varieties of strawberry-plants, cheap, for foundation or coo.
MRS. OLIVER COLE, Sherburne, Chenango Co., N. Y.

WANTED.—To exchange alfalfa seed and span mare mules, for nuclei and queens and basswood-trees.
BERT. W. HOPPER, Garden City, Kan.

WANTED.—To exchange bees, queens, and eggs (from B. P. Rocks, S. C. B. Leghorn, and Light Brahmas), for bee-supplies or offers.
CHAS. H. THIES, Steeleville, Ill.

WANTED.—To exchange some Bibles, albums, steel engravings, etc., for colonies or nuclei of bees, or offers.
W. T. ATKINSON, Auburn, N. Y.

WANTED.—Position in apiary, by man of experience.
L. H. GREENE, Wichita, Kan.

WANTED.—To exchange a 10-inch Root foundation-mill, good as new, for hives in flat, or sections 4¼x4¼, 7 to foot.
A. W. GARDNER, Centreville, Mich.

WANTED.—To exchange supplies and other goods for honey. O. H. HYATT, Shenandoah, Iowa. 20tf

WANTED.—To exchange several good safety bicycles. Honey wanted. Send sample.
J. A. GREEN, Ottawa, Ill.

I told you so.

Mrs. Atchley:—The one-frame nucleus I got of you last spring gave me 120 well-filled one-pound sections. J. A. SMITH, Heber, Utah, Oct. 9, 1894.

Now, haven't I told you that it will pay to send bees north in the spring?

One-frame nucleus, \$1.00; 10 or more, 90c each. Bees by pound, same price. Untested queens to go with them, 75c each.

Untested queens by mail, \$1.00 each; \$5.00 for 6; \$9.00 per dozen, till June; after, 75c each; \$4.25 for 6, or \$8.00 per dozen. I breed the leather-colored Italians, 5 bands, and Carniolans, in separate yards, at safe distance.

Tested, 3 bands, \$1.50 each; 5 bands or Carniolans, \$2.50 each.

Fine breeders of either race, or imported queens, \$5.00 each. Full colonies with untested queens, \$6.00.

Ask for discounts to dealers, and by quantities. The only steam bee-hive factory in south Texas. Root's goods, Dadant's foundation, and Bingham smokers.

Safe arrival on every thing guaranteed. Send for FREE catalog that tells all about raising queens.

JENNIE ATCHLEY, Beeville, Bee Co., Texas.

Woodcliff Business Queens.

To please all, am breeding both Leather-colored and Golden 5-banded Italians. Have five apiaries, 3 to 5 miles apart, running 350 nuclei. Your orders filled promptly. Can furnish queens from March 1st to Nov. 10. The Leather-colored 3-banded Breeder, imported from Italy, Oct. '94.

The Golden 5-banded Breeder, selected from 1000 queens, some producing 400 lbs. of honey to colony. State what you want, and send orders now for early delivery. Guaranteed queens, 75c; special low price in quantities. Send for descriptive catalog.

GLEANINGS IN A JOURNAL DEVOTED TO BEES AND HONEY AND HOME INTERESTS **BEE CULTURE** ILLUSTRATED SEMI-MONTHLY Published by THE A. I. ROOT CO. \$1.00 PER YEAR MEDINA, OHIO.

Vol. XXIII.

MAR. 15, 1895.

No. 6.

WHAT STATE SOCIETY of bee-keepers has the largest membership? Ontario?

VOGEL says the Egyptian bee is nearly tropical; and when 30° F. is reached, every bee in the hive is dead.

I'VE HAD VACATION for two weeks, even from bees, with almost nothing to do but sing. Makes me younger.

I FOUND some beautiful sections in Southern Illinois, stamped P. H. Elwood, Starkville, N. Y. Say, Elwood, you keep out of here.

I KNOW NOW, from that picture on page 167, what has become of Jake Smith. He got so puffed up with gas that he exploded. A warning for others.

THE LATEST cure I've seen for a bee-sting is from *Bienen-Vater*, a strawberry applied. I hope A. I. Root will no longer insist that strawberries have no use.

HONEY-DEW HONEY has a defender in Stanley & Son, in *A. B. J.* And no wonder; for in 12 years they have raised 80,000 pounds of it, selling it for \$10,000.

WHAT'S BEST for a cushion, a right soft one? At the rate they're settling the question of the size of hives, it looks as if I'd have to sit on the fence the rest of my days.

THE BIENEN-VATER says queenless colonies frequently fill queen-cell cups with jelly just as if occupied by larvæ, and build them out, sometimes almost a finger long.

J. E. CRANE, in *Review*, leaves the big-little-hive question all mixed up. In his home apiary small hives are best, and large ones 6 miles away. The different conditions account for it.

SACALINE is a Russian plant that is having something of a boom as a forage and bee plant. Director Wilson, of Iowa Experiment Station, says in *Stockman* that it grows 8 to 12 feet high in a year, but he has no hope of its being a for-

age plant, because cattle won't eat it, even in Russia.

MIEL DE NARBONNE, or Narbonne honey, which sells in Paris at 60c a pound, Baist, in *Noerdlichen Bztg.* says, is a white honey from apple-blossoms. Phin's dictionary says, chiefly from rosemary.

CARAWAY, says V. Wuest, in *Noerdlichen Bztg.*, is a fine honey-plant in his locality. But Editor Vogel says, although cultivated largely in his region he never saw a bee on it. How is it in this country?

B. TAYLOR says, in *Review*, that he has 10 hives with 12 frames, 20 with 16, and 12 with 19 frames. After giving them a fair trial alongside of 10-frame hives, he has thrown them aside as useless.

H. L. JEFFREY writes, "Things that I knew for sure 25 years ago I have learned are quite different now, and it takes years to know for certain but very little of any thing." You've got it about straight, H. L.

A HIVELESS COLONY is reported in *Deutsche Imker*, hanging to the roof of a bee-shed. It hung in the form of a hemisphere, built nine combs, making them far larger than the standard German frame, which is less than the Langstroth.

"DO BEES PREFER new or old comb?" is a query in *A. B. J.* One replier thinks they prefer new, three think they prefer old; three "don't know," and the great majority think they have no preference. Here's a nut for the experiment stations.

ACCORDING to Baron Ambrozy, at the big Vienna convention, the four notable steps of progress since Dzierzon's discoveries are, 1. The extractor; 2. Comb foundation; 3. The queen-excluder; 4. The improvement in the manufacture of honey-drinks.

WHEN I READ on p. 187 how nicely W. S. Hart has every thing arranged, and when I remember what a nice fellow he is, I can't help wondering why a man of such good taste should remain a bachelor. Or has he such critical taste that no woman comes up to the mark?

A PROJECT is proposed to establish at Paris an apicultural syndicate, not to divert the honey-market to Paris, but to secure that for which there is no market, manufacture it into *caux devie* and stamp it with the label of the society, to secure its ready sale on account of its purity.

"MR. FREEBORN's name was first brought prominently forward before the bee-keeping world through the Bee-keepers' Union." P. 183. Wasn't it the other way? I never heard of the Union till after Mr. Freeborn's troubles, and thereupon arose the Union. [I guess you are right.—ED.]

IT'S REFRESHING to see on page 183 that we're not going to be less enterprising than the Germans in the matter of adulteration. So much adulteration there is one of the reasons that thousands of the Rietsche press are in use, so bee-keepers can make up their own wax and know that it is pure.

DID YOU KNOW you can tell the time by a stem-winder in the dark? Wind up your watch, and an hour later wind it again, counting the clicks. If it clicks ten times, that means 6 minutes to a click. Then if you wind in the dark, and count 45 clicks, you'll know it's $4\frac{1}{2}$ hours since it was wound last.

"FLOHISTS have so highly developed the rose that it has scarcely any pollen, and I am not sure but some kinds are so double they are entirely destitute," says Somnambulist. That's putting it very mild. Very few of the better sorts have a single grain of pollen, the stamens being all changed into petals.

"I DO NOT BELIEVE," says S. E. Miller, in *Progressive*, "there is one cellar in fifty that is a fit place to keep either comb or extracted honey." No; and in the fiftieth cellar it would spoil in this part of the country. In Colorado, where I'm told bread dries in the cellar, it may be all right, and in other dry climates.

HONEY SOAP, so called, says *Deutsche Imker*, contains no honey whatever. If you want the genuine article, something that will keep your skin soft and free from chaps, make it yourself. Take one pound common hard soap, add rain-water, place the earthen dish with the soap in a water-bath, or on a stove-mat, and boil till dissolved. Then add an ounce of honey, and continue boiling till the water evaporates.

THAT ARTICLE on p. 124 is very interesting; but that part of the heading which says, "Small hives more profitable," hardly fits. Boardman's 9 frames, $12\frac{3}{4} \times 12\frac{3}{4}$ inside measure, are equivalent to $10\frac{1}{2}$ dovetail frames. [The heading to which you refer was based on the cubic capacity of the Boardman hive. Nowadays the 8-frame Langstroth may be considered a small hive. This contains the same cubic capacity as the Boardman, and hence I classed it among the small hives. But when we compare Board-

man's nine frames to the Dovetailed hive's eight, the case is a little different. One would not think there was so much difference in the capacity of the two frames; but I shall have to acknowledge that I can't find any thing wrong with your figures. But, say; Boardman doesn't use 9 frames or the larger capacity because it gives more room, but because he thereby lessens the burr-combs.—ED.]

PACKAGES FOR EXTRACTED HONEY.

BARRELS FOR COLORADO NOT SUITABLE; WHY SQUARE CANS ARE BETTER; CANDYING OF HONEY A SERIOUS DRAWBACK; REACHING CONSUMERS DIRECT; A VALUABLE ARTICLE.

By R. C. Atkin.

I have read with interest Mr. E. France's article on this subject, in Feb. 15th GLEANINGS, page 129. I have a little criticism to make, but mainly wish to add to what he has said.

My criticism is in the use of barrels. Keeping the barrels in a dry place, and well coopered before using, is all right. It is a fact, that a barrel kept in a cellar or damp place, when filled with honey, will season and let the hoops fall off just as if it were empty. In the fall of 1887 I filled two 25-gallon white-oak barrels, they having been kept dry for months before, having eight hoops *hard driven* just before filling. These I brought with me to Colorado. In a few weeks after arriving here I found the honey—*candied too*—leaking out, and I could pull the hoops off with my fingers. Had the honey been liquid I might have lost the most of it. That the barrels can be made tight enough to hold the honey, by his method, there is no question; but a barrel shipped from Wisconsin *here* would not remain tight. A few days ago I received a 50-gallon barrel of sorghum shipped for Eastern Kansas. It may not have been *thoroughly tight* when shipped; but right in zero weather, and exposed to the cold, it began to leak so that I have had to drive the hoops on it.

I have, the past winter, liquefied and marketed between six and seven tons of honey. It was in 60-lb. cans. I sold it to consumers very largely, it going here and there all over the country, in lots of from one to four or five cans. Few of the purchasers knew how to liquefy, or *were fixed* to do it. Now, had I stored this honey in barrels, then opened the barrels and *spaded out* the honey to liquefy in other vessels, then returned to the barrels to ship, I certainly should have decided never again to produce extracted honey. But should I put it into cans to ship, then I must have two sets of vessels—an additional expense. If I had a trade

that would take honey in such large packages, and take it *at the same price as in cans*, and provided I did not have to ship *empty barrels* a long distance so that the freight would be more than the first cost of barrel, and if I did not have to liquefy before shipping, I could use barrels. If the barrel could be kept from year to year, and the crop sold at retail, it *might* be a cheaper package in the end, for it will last for years; but if I have to spade out the honey and put it into other vessels, I should build a wooden, tin-lined tank that would hold my entire crop, and do it at much less cost than the cost of barrels to hold the same; or, what would be better, a metal tank with a heating appliance, and liquefy the honey in the tank.

Just recently I had quotations from Fish & Co., of Chicago, and they quoted one-half cent less if candied. Now if, to get the best price for the honey, it be necessary to liquefy, the barrel is not the package. Mr. France says his barrels cost \$1.50 for 370 lbs., which is a little less than $\frac{1}{2}$ cent per pound. Our cans cost us $\frac{3}{4}$ of a cent per pound. The freight will be some lower on the barrels. I have forgotten just the difference, but it is not much; but if the honey is to be liquefied to get the best price, the liquefying is much easier done in the cans. It is not necessary to take the screw-cap off when melting. The honey will swell some; but the degree of heat necessary—and above which it ought not to go—will not swell the can sufficiently to burst or kink it. I have a tank that holds six cans, and covers the top of an old range that I purchased and fixed up for the purpose, and I usually leave the six cans in this and covered with water, from 24 to 48 hours. If the heat be regular, and as high as is safe, 24 hours will do; but with a slow fire, and the temperature often low, 48 hours is necessary. I have kept the caps screwed tight, and they did not burst a single can in melting several tons the past winter.

Now, while I should much prefer the can, and think it the cheaper in the end, I have a criticism to offer on it. A 60-pound can is too large. Two cans in a box make a package that is *just too heavy and awkward for one man to handle*. We can have them boxed singly at a little additional cost, it is true; but this is not the only objection. Many people will order by the 25, 50, or 100 pound lots. It is so natural and easy to order in 25 and 50 pound lots, or multiples thereof, that it is often done; and then we must ship more or less, or else correspond and explain. Two 50-pound cans in one box are abundantly heavy, and I think there is no valid reason why they can not be had in these sizes.

There are still other difficulties in the handling of extracted honey. If it would stay liquid we could afford to ship in large packages, and take somewhat lower prices; but when we get at best only three to four cents above

freights and packages, then have to cut half a cent or more because it is candied, it is hard on profits. I doubt whether one commission or wholesale house in ten is fixed for liquefying. If the wholesaler can not melt it, then it must go to the retailer candied. Is there one out of twenty-five retailers who knows how and is prepared to liquefy? I believe that, in the whole city of Denver, there is but one firm—and that not on a business street—that is in any manner prepared to liquefy. The Denver commission men tell me they can not sell honey well in 60-pound cans. If a 60-pound package is too large, the 400 or 500 pound barrel would be still worse.

Now, if extracted honey sells in the general markets, and holds its place with other sweets, it must be put in shape to *handle cheaply and easily*. If I were a wholesale dealer in the city, I would demand that the goods be put in packages that I could handle as other goods are handled, or I would pay only such prices as would give me a margin over the cost of such packages and getting it into them. What the commission man wants, and what he must have if the product ever obtains and holds its proper place in commerce, is the goods put in such shape that it will reach the consumer in original packages. Until this is done we shall continue to do as we are doing—sell to consumers direct.

The producer of grains, grasses, and vegetables, and all manufactured goods, can sell his products at any and all times. There are regular dealers, and the necessary appliances for handling all these things. If the individual farmer had to advertise his products, and sell and ship to those who may want and need his product in other parts of the country, as many bee-keepers now sell their product, how much would he get out of his stuff? The city dealer does not go to the farmer for his products, but goes to the commission and wholesale houses. When he finds what he wants, it is in such shape that he can buy as much or as little as he wishes.

I suppose that C. F. Muth is thoroughly equipped for handling honey and putting it in retail packages. He, no doubt, can use large quantities of honey in large cheap packages; but the general produce-dealer can not do this, and must sell in original packages. I have the past winter, as previously stated, sold several tons of extracted honey. I could not sell it to commission houses nor to retail dealers. Why? Just ask your grocer to sell in *your own market, in cans and barrels*, and you will know why. The wholesale houses must have the honey in the very cheapest large package, and then put it into his own retail package, or the producer must put it into retail shape and all properly packed in regular packages before it leaves the honey-house.

Here again comes that snag of candying, and

also the fact that we must have an expensive sealing package. If the package be glass, we have increased freights. Retail packages that do not seal cost from $1\frac{1}{2}$ to 3 cents per pound; and those that seal, from 3 to 5 cents per pound. Add to this the freights, and the getting of the crop marketed is as expensive as raising it. Then after we have done all this, and the honey is marketed in nice shape, it candies before the consumer gets it. Some of our honey candies so quickly that, if it were transported long distances, it would be solid before it got there. So you see at every turn there is something in the way. With these difficulties in the way we must be content to let it remain as it is—extracted always at a disadvantage, and comb only a luxury—or find some better method of marketing.

We must lessen the cost of retail packages; ship so that we get low freights and commissions, and put the goods up so that the consumer gets it in the original package. What this package shall be I do not know; but certainly if we could put it into cheap tins, and seal, say, in something like the square oyster-can—a package that is so cheap as to be thrown away, as are those of all fruits and other canned goods—then with each can printed instructions to the consumer, that each one who uses it will liquefy for himself, we could then afford to raise extracted honey; and not only that, but find it successfully competing with other sweets, and holding its place. I could put up a large tank, and heating appliance, to hold a big crop; then if I get the crop I could buy the cans, and pack for market. The purchase of cans need be only what is needed. It would then make no odds if the honey did candy; for it would remain so until the consumer got hold of it. It would not bring quite so high a price in the retail market; but the intermediate expenses would be much less, and so benefit both producer and consumer.

I do not think that we shall altogether do away with glass; but the main crop must be in a very cheap package, and go to the consumer candied, the glass and fancy packages being left for the fancy trade. If this can not be done, then the trade in extracted honey must always be a very uncertain thing until it can be produced at a price less by considerable than the price of sugar. I say less than sugar, because of these difficulties in the marketing of it. It would be quite different if we could keep and handle the honey as easily as we do sugars. With a simple cheap package, and the goods sold to the consumer in the original package, it will become more and more of a staple and more and more a common article of diet.

Loveland, Colo., Feb. 26.

[This is one of the best and one of the most comprehensive articles on this subject that we have ever received, and I commend its careful reading to every producer. Barrels, whatever

may be their advantage in the Middle and Eastern States, are not suitable for a large part of the West, where the climate is dry, like that of Colorado and California. Tin or glass packages, or something that will not shrink, must be used; and, besides, as friend A. well says, they are more suitable for liquefying. We have tried spading the honey out of barrels; and we can't afford to buy in barrels, spade out, and liquefy, and run into smaller cans, and make any money out of it. But instead of spading, we find it cheaper to set the barrel in a large tub of hot water, and keep the water hot with a steam-pipe. But, few have the steam, and so the spade process is the one usually employed. But honey in square cans can be liquefied easily by any one. We set ours in a coil of steam-pipe.

We must, as producers, have our packages suitable for the honey-market, and, so far as possible, for the consumer. If it is true, that honey in barrels must be spaded out by the average commission house, and if he can't do it except at a loss, sooner or later he is going to make the producer pay for it in a reduced price. As square cans are so near the cost of barrels, per pound, it will be seen that they have a big advantage, not only in this one matter of candying, but in the fact that the bulk of honey can so easily be divided upon the multiple of 60 lbs.—Ed.]

RIPENING EXTRACTED HONEY.

SHOULD HONEY BE EXTRACTED THROUGH THE SEASON, OR LEFT ON THE HIVES TO BE EXTRACTED AFTER THE SEASON?

By E. France.

Mr. E. France:—Having read your articles in the late issues of GLEANINGS with much interest, I should like also to get your views, if I can, on one question that I have had upon my mind for some time. I believe Mr. A. I. Root advocates letting the bees cure the honey, leaving it in the hive until the latter part of the season, so it may cure well. It has also been our experience, that honey left in the hive toward late or until fall, is better in all respects than honey extracted, say, in June. I believe that you and a good many others extract at intervals during the whole season, commencing as early, even, as apple-bloom. Now, my question is, How do you manage to turn out a good article, extracting so early? or, how do you cure your honey? I should like to make or get out honey of the best quality, and am at a loss to know how it can be done without its being cured in the hive. I think I have seen in your writings that you put it in kegs as soon as extracted. I have read that curing in open barrels or crocks would be about as good, but I don't know. Do you extract any but that which is capped over? G. A. LUNDE.

Stoughton, Wis., Feb. 17.

[Mr. France replies:]

My friends, this is a big question; and an answer that would be all right for one place could not possibly work in some other location. Some locations have long steady flows of honey; others, a short heavy flow, a sudden stop, and then

all is over. The last is my condition. We will look at it from my standpoint, and let the other fellow answer for himself. Right here we never have any honey for the bees to work on to more than make a scant living until the middle of June. We have no fruit-blossoms to amount to any thing. Dandelion is the first for earliness. When the dry seasons have not killed the white clover, that will give the bees a living until about the middle of June. There may be a little honey gathered in the fall, and a little in the spring before the middle of June. But it is *all dark*, and but little of it. But one pound of it will materially darken 100 lbs. of white honey, so it is very important to go over all the combs and take out every ounce of this dark honey, at the commencement of the white-honey flow, so we have extracting No. 1, or, as we mark it, one X. It is dark, and most of it goes to the baker's.

Now we have emptied our combs of the dark honey. But we have not washed out the combs; and, do the best we can, there will be enough of the dark honey left to shade. The next extracting is No. 2 as to color. If the honey is coming in pretty fast, the combs will be full in a week or ten days. If the weather has been fair, and not much rain, the honey will be thick and good—about two-thirds capped over. We must get this extracting out, for the same reason we did the first, for from now on until the close of the basswood season, we get our whitest honey; and now, if we are to get a good crop of honey, the bees are doing their best, and will fill their combs once in a week. Assuming that the bees have three sets of eight L. frames, or their equivalent in some other frames, if we empty the combs once a week we can go right along with the second set of extracting-frames. If it is a good season they can be extracted three times yet, making five extractings in all. The honey will be good if the season is not wet. If it rains much or often, then we have to wait longer between extractings.

We will now see how it would work to wait until the close of the season, as above, extracting thrice during the heavy honey-flow. We shall have to empty 6 sets of L. frames, if we wait until the close of the season; or, in other words, we shall have, at the close of the season, including the brood-nest, seven stories of combs. How about the wind blowing them over? How many of us are prepared to keep over that many empty combs, if we had them? If we have 100 or more colonies, we shall have to have a big pile of extra supers and extra combs. If we extract at the close of the season, the bees will be cross, and get every one on the steal, and we shall have the biggest robbing-scraps you ever saw, unless extra care is used. No greenhorn can do it; and how about the empty combs, after they are extracted, all sticky with honey? What are we to do with them—put them away in that condition, or

give them to the bees to clean up? If the bees are to clean them, not one man in ten will do it without getting the bees to robbing. Well, what are we going to do about it? For my part I am going to extract while the bees are gathering honey. I get no fall honey. My bees have to winter on basswood honey, and we must quit extracting in time for them to put up their winter supplies. We put our honey in barrels, right in the yards, as it comes from the combs; drive in the plugs, take the honey home, and deposit it in our honey-house. We don't loosen the plugs. We don't extract thin honey. We wait for it to get thick enough to keep well. We don't wait until all is capped, but only from one-half to two-thirds. When the weather is very dry, honey may be extracted as soon as gathered, and be good. Of course, when we are extracting we get some honey that was gathered the same day, and some the day before; but how can we help it? If it averages thick and good, and will keep sweet, that is all we can expect. We sometimes have honey that sours more or less. We don't sell that for first-class if we know it. The bakers can and do use sour honey, and they buy it. They say it takes more soda or less acid to make it work right.

Platteville, Wis.

MANUM IN THE APIARY.

SECTION CARTONS; WINTER VENTILATORS.

By A. E. Manum.

"Good-morning, Charles. It seems to me you are out in good season this morning."

"Yes, Manum, I find myself confronted with a little difficulty this morning, and I have called to consult with you. As you know, our cartons came last Friday afternoon, and this (Monday) morning my helpers all came in good season, as we were intending to get my honey all ready to car with yours Tuesday, as you and I had agreed upon, and I learn the freight-car we had ordered for the purpose is already at the station in waiting for us. But upon going to work putting the sections of honey into the new cartons I found that the latter were too small. We opened all the boxes, and tried some from each box, and found all alike—too small—and I have come over to see if yours are likewise too small."

"No, Charles, mine are just right; and, as you see, my honey is all crated and marked, and ready to ship."

"Now, that is very strange, Manum. Your cartons and mine were ordered at the same time, and of the same firm. Our sections are just alike, and my cartons are too small, while yours are just right. Well, here; I have brought over 20 of mine for you to examine."

"I declare, Charles, they are too small, sure enough. That is too bad. We have waited

and waited for the manufacturers to get them out until we have lost the best of the market, no doubt, as it has been my experience that the first honey put upon the market usually sells for the highest price; and, furthermore, we have arranged to ship our honey together by *freight*, to save expense, rather than ship separately by express. But here we are—mine is ready, while yours is not, and is liable not to be for some time if you have to order more cartons made, which I can see no other way for you to do under the circumstances. It is very unfortunate, to say the least, as it is a damage to us both, especially to yourself."

"Now, Manum, what would you advise me to do?"

"Why, Charles, I would telegraph the parties that these cartons are too small, and to make you another lot at once."

"Yes, that is my only way out of the scrape; and in the mean time you might as well ship your honey at once, and not wait for mine; and I will see the station agent on my way home and countermand the order for the freight car, as you will doubtless ship your honey on the butter-car to-day."

"All right, Charles; that is our best way out now, as the matter stands. Hereafter, Charles, I think it will be policy for us to order our cartons early in the season, and of the *old firm*. They have always been prompt and reliable. Suppose we order one or two thousand more than we need the present season. They are not very expensive, and are something that will keep without shrinkage. I have learned, Charles, by sad experience, that it is bad policy to leave an old and reliable firm—such as the A. I. Root Co., for instance—and dodge off on some side branch, expecting great things. Nine times out of ten the tender branch will let us down with a *thud*, as you have just been let down."

"Yes, that is right, Manum—just right. I want to know what you are doing with those pieces you have piled up here on your bench."

"Oh! these are for winter ventilators, to take the place of quilts; you know that quilts are more or less a bother. To begin with, the bees will cover them with propolis in a year or two so that they are no better than enameled cloth or boards, to allow the escape of moisture; and, furthermore, the bees gnaw holes through them in so short a time that I find it quite an expense to renew them every two or three years; and, again, if the wind blows—as it usually does—when packing or unpacking the bees, these cloths will be scattered all over the yard if left on the ground or a hive; and, also, by the use of quilts, when putting them over the frames the whole brood-chamber has to be uncovered, thereby disturbing the bees and permitting the warmth to give place to cold air, since we have always chosen a cool day to pack the bees, owing to the fact that, in a cool day, they are

more apt to be compact and at the bottom of the frames, making it much more convenient covering them with the quilts than in a warm day when the bees cover the top-bars. But with an arrangement made thus I can not only

MANUM'S WINTER VENTILATOR.

pack my bees in less than half the time that it would take with quilts the old way, but they are much better, as they will last a lifetime, and cost no more than cotton sheets—called quilts. To use them, all I have to do is to separate the two honey-boards two inches apart and place these ventilators between them and cover all with the thick cushion."

"Yes; but, Manum, suppose one does not have his honey-boards—cover to brood-chamber—in two parts as you do; how can he use these ventilators?"

"Oh! just simply by shoving the board to one side and placing the ventilator at one end instead of in the middle of the brood-chamber; and besides, Charles, they can, in case of emergency, be used as feeders. By placing them with wire screen downward the space can be filled with moist sugar, which would keep a starving colony alive for a day or two, or until they can be fed more abundantly."

"In this case, then, what are you going to do with your old quilts?"

"Charles, when I visited our friend J. E. Crane last spring I learned what to do with them, whereby I am putting them to good use by using them for smoker-fuel. I can tell you that, with my Crane smoker filled with well-politized rags, I can drive bees home or mad dogs out of the streets."

Bristol, Vt.

REPORT OF THE CALIFORNIA STATE BEE-KEEPERS' ASSOCIATION.

By J. H. Martin.

The California State Bee-keepers' Association held its annual session in the new Chamber of Commerce, Los Angeles, on the 5th and 6th of February, 1895. After the preliminary routine the subject of marketing honey was taken up for general discussion. The trend of the discussion was toward coöperation and the establishment of exchanges for the purpose of handling honey. Fruit exchanges were proving a success, and why not have success in the sale of honey also?

Mr. McIntyre seemed to have an exchange of his own, which was working satisfactorily, as he always sells his honey for not less than 6 cts.

per lb. His plan is to hold his honey until he can get his price.

Capt. Wood sold the most of his honey in the home markets, and would not sell for less than 6 cts.

There were some pertinent remarks in relation to the commission men and their practices, and it seemed to be the desire of the bee-keepers to get along without the commission men, and to get into a more satisfactory way of disposing of the product.

In the afternoon session Mr. Brodbeck read a paper upon the coöperation of bee-keepers, which was followed by a long discussion.

SELLING HONEY ON THE COÖPERATIVE PLAN; GIVING COMMISSION MEN THE GO-BY.

Mr. Mellen cited the fact that a coöperative store had been organized in the town of Acton, which was a success. Coöperative stores are being established all over the country. These coöperative associations act together; and if the sale of honey could be effected through such organizations we could secure better prices for it. At present we are at the mercy of the capitalist, and the coöperative plan is the best way out of our difficulties.

It was stated that plans were in progress toward forming some such organization in Los Angeles for the purpose of handling honey; and if the coming season should be a bountiful one, as the abundant rains indicated, it would be a good season to start such an organization. The exchange, or whatever it may be named, should have an officer at the head of it. Every producer who would support the organization should state the amount and quality of his honey, and attach his name to every package. The officer of the association has samples only in his hands, and secures orders from these samples. This obviates the necessity of storing large amounts of honey in any given warehouse, with its attendant expense and risks.

Bee-keepers, instead of putting their honey into five-gallon cans exclusively, should use a greater variety of packages. Some recommended one-pound cans, and all the way up to the standard five-gallon.

Prof. Cook said that great corporations held together as one man. The laboring men should in like manner hold together. He believed the time was coming when the laboring men would do this, and better prices would result. Have patience, and agitate. The producers are too suspicious of each other, and so scattered that the coöperative plan had not been adopted. The fruit-growers had been compelled to organize, and the result is better prices for their fruit. It needs enthusiasm and some self-sacrifice, perhaps.

The great fundamental principle is, to first establish a good price and stick to it. The fraternity were greatly handicapped by so many needy bee-keepers who are obliged to sell their honey in order to purchase the necessities of

food and raiment. If an organization is formed it must have a little capital to enable it to advance some money to this class of producers.

Capitalists are afraid of coöperation, and will hinder its establishment if possible. The professor did not believe in the mushroom growth of such organizations. A slow growth gives it a more substantial footing.

Mr. Touchton said that California honey had to compete with the whole United States and Cuba. He thought that an exchange, however small, if once established, would grow. This would lead to putting up honey in such packages as the public demanded. Each producer should keep his own brand on his packages, and thus make a reputation.

Mr. Wilder thought that California honey should bring as good a price as eastern, and he proposed to take a carload east and sell to the consumer. He believed that but a small portion of California extracted honey found its way to the tables of eastern consumers; it is used largely in manufacturing establishments; and, coming in competition with sugar, when the price of honey advanced above a certain figure, sugar is used instead.

Mr. Flory said that Central California bee-keepers were ready for coöperation. They were subject to low prices, high freight rates, and an unjust tare on all of their packages; upon a crate for comb honey weighing only 4 lbs. they were obliged to allow 7 lbs. tare, or an actual steal of 3 lbs.

An expression of the meeting was taken in relation to organizing on the coöperative plan; 15 arose in favor of it and 6 against, while there were several not voting. The 6 had facilities for storing their honey, and were able to keep it until their price, 6 cts. per lb., was obtained.

BEE-PARALYSIS SCARCE IN CALIFORNIA.

The next subject under consideration was bee-paralysis. The opinions upon this malady were somewhat contradictory: Locality had much to do with the opinion in relation to the cause. The fact was brought out, however, that there were but very few cases of paralysis in California. Several bee-keepers, owning their hundreds of colonies, had observed only three or four cases at any one time in their apiaries. The disease usually disappeared when new honey began to be gathered.

Mr. Touchton gave a lecture upon practical bee-keeping, demonstrating his remarks with a hive and all tools for management. There were some criticisms upon some of the methods; but on the whole Mr. Touchton, being a practical bee-keeper of many years standing, his ideas were generally indorsed.

The evening session commenced with an excellent annual address by Pres. A. J. Cook.

Several of the points brought out in the address were discussed. The so-called new bee-disease, also the controversy between fruit-

men and fruit-dryers and bee-men. City ordinances against producers selling their own products were pronounced unconstitutional.

A paper upon California bee-keeping was read by J. H. Martin, after which there was a social half-hour. The convention was favored with the presence of the Hon. J. M. Hambaugh, of Illinois, and Mr. Jacob Alpaugh, of Canada.

Wednesday morning the swarm of bee-keepers were a little tardy about convening. Mr. Mellen read a paper—Money vs. Honey. Mr. Mellen touched upon financial things generally, and thought that a better financial policy for the nation would result in financial accumulations of the bee-keeper.

The use and abuse of smoke in handling bees was next treated by Mr. Mendleson. This called out quite a lengthy discussion, all tending toward careful handling, clean hives, with a clean apiary.

The fact was also noted that bees, while gathering honey, are more vindictive than under the same conditions in the East.

The discussion led into the feeding of bees. The past season had been one in which the bee-keeper could experiment to the extent of his ambition. Honey, diluted honey, sugar (refined and raw), beet sugar, and Chinese sugar, had all been used with success. A few gave preference to diluted honey.

The methods of feeding were as various as the kinds of feed. The most rapid way to get over a large number of hives was to pour the feed into empty combs and place them in the hive after dark.

Capt. J. M. Wood next brought in an old red weather-beaten hive, and lectured upon the advantages of his method of management. His frame was about the size of the Gallup. His tools to manipulate the hive were of his own invention and manufacture. A scraper, something like an intensified putty-knife, seemed to be a very handy tool. His smoker was the old-style Root Simplicity, improved according to Wood, and in which he used a ball of sacking for fuel. His honey-knife was also constructed with an abundance of metal that would hold heat, when warmed, for uncapping combs. For heating the knife a copper boiler of unique construction was used. Upon an expression of the meeting being taken, Messrs. Wood and Levering favored the Wood system, while all of the rest of the bee-keepers favored some other way.

The Bingham honey-knife was also indorsed as the standard knife.

Mr. Cory exhibited a knife invented by himself. This was also a heavy knife, and a trifle curved at the point, long enough to uncup a L. comb at one stroke. The method of cutting down and then up was illustrated.

The question-box was at this point introduced; and in answer to the question as to the best average of honey in the best season, Mr. McKin-

tyre said his opinion was that the average for a number of seasons in the best apiaries was 75 lbs. per colony.

The afternoon session was devoted to the election of officers. Prof. Cook was unanimously reelected President.

J. H. Martin was reelected Secretary; H. E. Wilder, Treasurer.

Mr. McKinney,	Vice-pres. for San Bernardino Co.
Mr. Brodbeck,	" " Los Angeles "
Mr. Flory,	" " Kings "
Mr. Taylor,	" " Riverside "
Mr. Touchton,	" " Ventura "
Dr. Gallup,	" " Orange "
Mr. Stubblefield,	" " San Diego "

Reports of committees followed.

It was voted to pay the secretary \$25 for services.

Also voted to pay from the treasury the sum of ten dollars to the Langstroth fund. This was further increased to \$16.60 by a collection. Dr. Gallup, an old-time bee-keeper, and now living in Santa Ana, then made a few stirring remarks, proving that, though out of the business for years, the bee still could arouse his enthusiasm.

Upon motion of Mr. Brodbeck, the Central California Bee-keepers' Association was recognized as co-workers with us; and their action in sending such an able representative as Mr. J. F. Flory was commended.

The Association then adjourned to meet at Los Angeles at the call of the executive committee.

PROF. A. J. COOK, PRES.

J. H. Martin, Sec., Bloomington, Cal.

SEPARATORS.

THE ADVANTAGES IN THE USE OF NARROW SECTIONS; CLEATED SEPARATORS.

By B. Taylor.

Editor Gleanings:—I send you to-day one of the separators I have been using for four seasons. In looking over your price list I noticed that you mention a cleated separator in which the entire bee-space is in the separator, thus leaving the honey in the section two bee-spaces thicker. You will notice that my separator has

TAYLOR'S SEPARATOR.

only a half bee-space in it; and the reason for this I will tell further on. I have often put myself on record as having no use for separators, always having the combs straight enough to crate conveniently without them; and I always viewed cutting a super up into a little separate room for each section (which the separators in use did) as discommoding the bees, and I still

think so. But several years ago I discovered the great value of empty drawn combs in sections, for getting a large yield of white comb honey, and I found it impossible to get such combs filled and capped evenly enough to make their use possible. So I began to experiment on a separator that would obviate the objections I had to those in use. I wanted a separator that would leave a free passage for the bees, in the center between each section, and thus avoid partitioning each section off by itself, with a solid partition wall. This I accomplished by making the separators of two thin strips, and cleating so as to leave a scant $\frac{3}{8}$ space or slot between them lengthwise.

Now, there was another thing I wanted; and that was, to use narrow sections—some not more than $1\frac{1}{2}$ inches wide. I had been using these narrow sections for twelve or fifteen years, and I liked them so well that I could not think of abandoning them. I had changed all my supers so as to use sections 4×5 inches, and $1\frac{1}{2}$ wide. These sections, when filled without separators, come nearer a pound than any others I ever used; and let me say here that narrow sections will vary far less in average weight than wide ones. But my narrow 4×5 sections, with separators between, so a bee-space would have to be taken from both sides of the combs, would leave them but one inch thick, and they would not weigh $\frac{3}{4}$ of a pound, and this would not do. So I began to study a way out of the difficulty. My first thought was to cleat the separators like yours, with a whole bee-space in the separators; but from theory alone I saw this would not do, for two reasons. First, the combs would have $\frac{1}{4}$ inch added to each side, and would weigh more than a pound. I could have remedied this by making the sections $1\frac{1}{4}$ inches, or less, wide; and as I loved narrow sections I would have gladly changed in that direction; for with the whole bee-space in the separators I could have all four sides of the section the same width, which would be an advantage; but the second reason could not be settled so easily; for, with a full bee-space in the separators the combs would be built as thick as the sections were wide. The edges would be built right up to the cleats on the separators, and would be sealed more or less to them, and would break the cappings on being removed. I tried enough to know that this one fault would render separators with full bee-spaces in them impractical.

There is another objection that would prevent their use. The combs being as thick as the sections, in crating, the surfaces of the combs would touch together, chafe each other, and start the honey to leaking. With the aid of the comb-leveler I could dispense with separators in using drawn combs in sections; but I have now used them, like the one I send you, four seasons, and I like them so well I probably shall never fill another super without them. I

do not use them between every section—only between every two. This gives perfect sections that weigh a scant pound each when filled. The honey on both sides of the section comes within $\frac{1}{8}$ inch of the edge of the section, and is never broken in removing the separator, and the surfaces are $\frac{1}{4}$ inch apart in crating. In crating sections filled between common flat separators, the surfaces of the combs are $\frac{1}{2}$ inch apart, and require a larger crate for the same number of pounds.

You will, no doubt, ask why I make my separators $\frac{3}{8}$ thick. I tried thin ones of wood, and the bees soon gnawed and spoiled them. Those $\frac{3}{8}$ thick cost but little more, and, made like the one sent, will, with proper care, last a lifetime, and prove cheap indeed.

I see narrow sections are attracting the attention of bee-keepers. They have so many good points, when tried, that they will yet cause the $4\frac{1}{4} \times 4\frac{1}{4}$ section to be abandoned, for they are too small to hold any thing near a pound, if only $1\frac{1}{2}$ inches wide, and this is the extreme width of the coming section. The combs are fastened to all sides of $1\frac{1}{2}$ sections much better than to wide ones, and ship more safely with the separator I use with its slotted center, so the bees have free passage from comb to comb, without having to leave passages in the corners of the combs; and with narrow sections the combs are made solid to every side, and nearly every cell will be sealed; and these sections, with their larger surface, and filled to $\frac{1}{8}$ inch of their edges, solid fast on all sides, and every cell sealed, make a section that leaves the wide $4\frac{1}{4}$ section, with its sunken surface and imperfect capping and fastening, far in the shade.

Some years since, Mr. Keys, of the firm of James Fornerook & Co., visited the Forestville apiary. I took him into my honey-house, and showed the well-filled sections of $4\frac{1}{4} \times 4\frac{1}{4}$ size, $1\frac{1}{8}$ inches wide, and the $4 \times 5\frac{1}{2}$ sections, and he agreed, without argument, that the latter made a much finer appearance, and looks go a long way in selling comb honey. So impressed am I with the superior advantages of the larger and narrower sections that I would not accept as a gift a future supply for all time of $4\frac{1}{4} \times 4\frac{1}{4}$ and $1\frac{1}{8}$ sections.

Forestville, Minn., Jan. 22.

[I am well aware that there are advantages in the use of narrow sections. The combs are filled out better, honey ripened perhaps better, and customers will take them, because, while they appear to be as large as the regulation $1\frac{1}{8}$, they are cheaper. In Canada, the 7-to-foot and $1\frac{1}{2}$ section rather take the lead; in this country, $1\frac{1}{8}$; in England, full two inch, but all $4\frac{1}{4} \times 4\frac{1}{4}$ in size. But you probably do not overlook the fact that, while you may be able to get more for your 4×5 sections, as a general rule they list in the market quotations, or did so, at least, until they were driven out of the market, from one to two cents lower than the regular $4\frac{1}{4}$ size.

I believe your separator is a good thing. It

certainly would greatly improve the T super; but cleated separators, you are probably aware, are not new. In Nov. 1st GLEANINGS, 1888, p. 833, Oliver Foster set forth their advantages. His article was accompanied with an engraving which, for the convenience of our readers, we now reproduce.

You will notice it is not exactly like yours, but it embodies the same principle. The cleats on both sides are half a bee-space thick.

Mr. J. E. Crane, of Middlebury, Vt., is another bee-keeper who has been enthusiastic, I believe, in the use of the cleated separators. When I called on him in 1890, on that bicycle trip, he showed the advantage of this sort of separator in connection with sections having no bee-ways or openings, the bee-spacing being entirely provided for by separator-cleats.—[Ed.]

CALIFORNIA ECHOES.

By Rambler.

At the recent California State convention of bee-keepers, Prof. Cook called out quite a number of test votes. In the use of quilts of various kinds over the frames, 19 had used them, and now only 9 of the 19 use them, showing that 10 had discarded the useless, mussy things.

California bee-keepers are invited to make exhibits of their products in the Chamber of Commerce. An attractive display here of several feet of floor space would be a standing advertisement of California honey. People from all portions of the earth are visiting the Chamber daily.

The bee-escape was considered not so much of a success here in clearing an extracting-super as it might be. The escape clears the super of bees; but the honey, deprived of its warming factor, gets cold during the night, and is extremely hard to extract. What we want is something to clear the super as quick as a brush would do it, or from three to five minutes.

Mr. Brodbeck had one of his hives in the Chamber of Commerce. Mr. B. has taken a step in the right direction. He uses the Dove-tailed hive with Hoffman frame; but hive and frame are shallower than the standard, by an inch or more. That's right, Mr. B. You will soon progress to the use of the shallow divisible brood-chamber.

The rainfall up to date in the San Bernardino Valley amounts to 17 inches. This, with a few inches in March and April, will probably insure a honey crop. But even after profuse rains, there are sometimes climatic influences at work to prevent the secretion of nectar. These extraordinary influences, however, appear so seldom that plenty of rain gives great buoyancy to the spirits of the bee-keeper.

"Skim-milk queens" was a very happy term applied by Mr. McIntyre to those queens reared under the forcing plan, and where the royal jelly is thin and scarce. Skim-milk queens and successful honey production do not work well together.

In this valley, thousands of acres will be planted to what has hitherto been considered a worthless plant—canagrie, with the newly discovered tanning properties. Reliable authority claims that it does not yield honey. Perhaps, with thousands of acres, the bee will find a sustaining forage upon it.

In these days of foul brood, bee-paralysis, etc., it behooves bee-keepers to be very careful about introducing queens, honey, or second-hand hives into or near their apiaries. Our most successful bee-keepers breed nearly all their own queens, and would not feed honey bought up promiscuously, under any consideration. A pastor of a Disciple church informed me that such a purchase of honey, and a feeding of it, inoculated his whole apiary of 50 colonies, and he lost them all. His experience was brief but pointed—spent 400 dollars on bees; never received a cent in return. Moral: Be careful what you feed your bees.

RAMBLE 128.

AT BLACK DIAMOND.

By Rambler.

Mr. Jones, collector for the Pacific Gas Improvement Co., a few evenings after our call upon his quarrelsome bees, reciprocated, and sat down with us by our camp-fire. We found Mr. Pryal an adept at keeping up the flames. We had been chaffing him some about the raw and foggy condition of the nights around the Bay, and had urged him to visit the more salubrious clime of our sunny Southland. Of course, like a true native son his Oakland possessed the best climate in the world; and then he would emphasize his remarks by throwing another armful of brush on the fire. Where nature requires so much aid in August to keep up a comfortable warmth, it is indeed pleasant to find such an efficient helper.

Around the fire the conversation circled; and bees, best locations, hunting deer, bear, and even hogs and their profitable culture as a side issue with bees, was discussed. Mr. Jones thought a hog-ranch out in the free air of the country preferable to those everlasting side-walks and tall brick buildings. A good apiary in connection with it would just profitably round out the season.

Pryal and Wilder held a grand idea that, when prices in pork and honey ruled low, the hog might be raised profitably for its bristles. For instance, a tooth-brush is sold for 15 cents and upward; a good-sized hog, with his back well cultivated, would yield bristles for a

thousand tooth-brushes. In view of the bonanza before us I had only one suggestion to make; and for the moment I was inspired to put it into rhyme, as follows:

That is right, Bro. Pryal;
On the fire put a log,
And by the cheerful flames
We'll view the festive hog.
You may make him into bacon,
Or fry him in the pan,
Or his bristles use for brushes,
But here's a better plan:
Your highfalutin schemes,
Like mice and men, will fail,
Unless advice you take—
Make whistles of his tail.

This ended the hog discussion for the evening, and our convention resolved to adjourn. It

As we climbed and climbed the moderate mountains, the landscape grew behind us, and we were soon at such an elevation that the cities, the bay, the islands within the bay, the Golden Gate, and the broad ocean, were spread out before us in one grand panorama; and when we consider that a genial clime touches with its magic wand the vegetable world, and gives one round of growth and bloom from one end of the year to the other, it is no strange thing that people enthuse over the wonderful climate of California.

We are now in Contra Costa Co., and we drop down on the north side of the mountains; and 18 miles from Oakland we halt for a few days in Walnut Creek, a pleasant little town. Hard times seemed to be knocking at the doors of the majority of the people. The saloons, how-

PUMPING WATER TO SPRINKLE THE HIGHWAYS.

was hard upon 12 o'clock. Mr. Jones disappeared in the darkness with a kind farewell, and we made an opening in the fog and sought our tent.

The days sped by so full of duties and pleasures that a week elapsed ere we were again ready to proceed on our journey. Our evenings of social converse with bee-keepers, and especially in the Pryal home, when the family gathered around the hearthstone, and, aside from the words fitly spoken, there was vocal and instrumental music in the air—those evenings will not soon be forgotten; and on the 11th of August, when we took our departure, and climbed the hills that rise abruptly in the rear of Temescal, I cast glances below and exclaimed in heart-felt tones, "May the shadows of all the Pryals never grow less!"

"Amen!" says Bro. Wilder.

ever, seemed to be doing a good business—even better than the churches. Spending Sunday in town I patronized the little M. E. church, and found 40 in attendance. At the close of the services there seemed to be a greater crowd and more lively times around the saloons. The pastor was young and earnest, and dispensed the word with ability. Still, there was apathy in the outside crowd, that left the church with a meager attendance.

Spaniards and Portuguese were numerous here, and the Spaniards often indulged in a barbecue. We camped near the scene of their festivities. In a shady nook on the banks of the little creek the Toro Club assembled occasionally to eat the face off a bull's head and crack a few bottles of vino.

The master of ceremonies, the barber of the town, came around to prepare for one of these

gatherings. We had noticed a deep hole in the ground near the creek, and curiously wondered what it was used for. It was 4 feet deep and 3 feet in diameter. Our barber built a fire in the bottom of the hole, and kept feeding it with hard-wood chunks until there was a thick bed of coals. A bull's head was then carefully rolled in a burlap sack, and dropped upon the coals. Immediately the head was covered with dirt to the depth of about three feet. From 16 to 24 hours was considered long enough to cook the head. It was then taken out piping hot. The Toro Club would assemble around a rustic table, under the walnut-trees, and enjoy the festal board.

Our camp was furthermore enlivened by its proximity to the cooler, made necessary by the aforesaid saloons. The cooler was very appropriately located near a huge water-tank. It was the duty of the waterman to put his three docile horses to the turntable pump and fill the tank regularly every day, and as regularly every night deliver it to the thirsty and dusty road all about town.

There were no bee-keepers here to enliven our evenings, and with whom to trade jokes. We longed again for Bro. Pryal's camp-fire and Bro. Jones's enthusiasm. We knew, too, that they would enjoy the numerous mosquitoes just as we did. We realized the full beauties of cool foggy nights, for the result was fewer mosquitoes in Oakland, and a double portion in Contra Costa Co.

When the days were fulfilled for us to move along we left Walnut Creek in peace, and next surprised the town of Black Diamond. This queer little town is located on the Suisun Bay, at the point where the San Joaquin and Sacramento Rivers mingle their chocolate-colored waters. We expected to cross the bay immediately; but the town was so inviting we resolved to stop a few days. The streets were not as inviting as they are in some towns in which we have been; for numerous pigs, goats, dogs, and urchins ran at large, and preyed upon the unsuspecting camper. Black Diamond, as the name suggests, derives its name from coal-mines in the hills beyond; but the mines have been paralyzed by a ten-years' litigation. Salmon-fishing, however, is a flourishing industry, and several score of Italians reside here, and daily mend their nets, and nightly go forth to swoop in the fish, which they do by the boatload. Canneries dot the shores of the bay, and the business of putting salmon in cans is nearly as honorable as the production of honey. The Dagos, however, even if they did come from the land of our gentle Italian bees, have not

that sweet disposition so characteristic of the American bee-keeper. The Dago wives are sharp-tongued, meddlesome, and saucy. Their pigs, their goats, their urchins, and mosquitoes, were ditto. Saturday night the fishermen all came in for a grand pow-wow, more than less; wine was guzzled, and Italian language was slung through the air in volleys, salvos, and broadsides. We know, for a whole brigade of Dagos hung to the fence near our tent, and fired words at each other until one volley knocked a fellow over our tent-rope. Well, now, wasn't there music! Our lantern came rattling from its hook; Wilder yelled, and I did. The meeting outside was broken up in confusion, and the participants scattered to the four winds of Black Diamond. One of the

DAGO FISHERMEN AT BLACK DIAMOND.

Dagos was, however, polite enough to hug himself into a comfortable feeling. He came back and apologized. He explained a fact that we already knew—that the rest were all drunk. Between Dagos and mosquitoes, we slept but little that Saturday night.

Sunday I found peace and quiet in the little Congregational church. A young and earnest pastor preached a helpful sermon; but his audience was small, and the cause languished. On the public square, in sight of our camp, however, that afternoon times were very lively. There was a baseball game, and a hundred and fifty people in attendance.

Contra Costa Co. can not be classed as a honey-producing locality. About the only bees we find are in nondescript hives, and few in number. Mount Diablo (devil) in the eastern portion of the county should bear upon its sides a rich honey-flora; but from its name, or some other cause, Mount Diablo is not worth much if any thing, in a practical way. There are, no doubt, good locations along the San Joaquin River which could be made profitable with fruit-raising. That these places may soon be occupied by some happy bachelor is the wish of the Rambler.

T SUPERS.

WHY BETTER THAN SECTION-HOLDERS OR WIDE FRAMES; THE PROPER WAY TO MAKE A T TIN.

By A. B. Anthony.

I have produced comb honey in several styles of surplus-cases; and if I could have the T tins made as I like them I should like the T super best. Two-tier wide frames are away behind, because the valuable feature of tiering up is lost. Single-tier wide frames are good, but they can be rigged for only one width of sections, and then if made for separators they can not well be used without. Pattern slats, or bottom-bars, are a slight disadvantage because they place the sections that much further away from the brood-chamber. Could they be above the sections their clean tops would be valuable. As for the bottoms, no one hardly ever sees them.

T tins as I use them are fastened permanently to the crates. Simplicity should be the rule with all fixtures a bee-keeper has to deal with. Section-frames make extra pieces: separators, that many many more. Some think that shifting section-frames will pay: I think not. I used to do that too, but don't any more. A super should be suitable for sections open on all four sides.

We, the majority of bee-keepers, I believe, have always been wrong in the use of closed-end sections and open-end brood-frames, where we should have had open-end sections and closed-end frames.

I think, also, that those of us who use separators, and get ordinary prices for our honey, do so at a loss. One great trouble is, that we use sections that are too wide. The T tin that I think would be more suitable would be like the diagram above. The worst trouble with the old T tin is, that the rounding at the point 1 took up so much room as to separate the sections. The T form is a strong one. By using thin tin, and bending as I suggest, it would leave hardly a visible space between sections when compressed. Also, the points 2 2 would not form cutting edges for hands and fingers, and would never become bent out of shape as much as the old kind do.

I hope, Mr. Root, I am right in the above, and that you can see it so. Of course, a new machine would have to be gotten up to bend this form. If some of your help could turn out one to make these tins I should be pleased to have it so; and if they should fail, and you really felt that you wanted one, perhaps I could try for you.

Coleta, Ill., Dec. 17.

[So few, comparatively, use T tins now that it is a question whether it would pay us to build a new machine to make the tins as you recommend, providing we admit that they are better when so made. Of course, I see that it might be an advantage to have the point 1 as thin as

possible; but there is no reason why it can not be just as thin when constructed the usual way. On the other hand, are we sure we want them thin or flat at the upright? If we could reduce it to nothing, it would be desirable. As we can't, is a thickness of $\frac{1}{32}$ any worse than $\frac{1}{64}$? and is it not true that separator stuff will close up a space of the former on top of the sections better than in the latter? How is this, Dr. Miller?—ED.]

TIERING UP FOR COMB HONEY.

SHALL A SUPER OF EMPTY SECTIONS BE PUT UNDER OR OVER ONE WITH SECTIONS PARTLY FILLED?

By John Handel.

Editor Gleanings.—At last Dr. Miller knows (see *Stray Straws*, p. 8), where he says: "The abuse of a good thing is no argument against its proper use. Like John Handel, p. 944, I've coaxed bees up into the eighth" (I said sixth) "story, and had all unfinished sections; but, all the same, when I'm pretty sure bees will fill a second super, I put the second one under. If doubtful about both being filled, I put the empty one over."

Now, why does Dr. M. "allee samee" waste his strength lifting heavy supers off the hive and on again? We will take "don't know" for an answer, doctor, but give us a reason if possible. I know the practice is backed up by age, and numerous followers, but that is no evidence of truth. We should prove all things and hold fast that which is good. I have proven (to my satisfaction at least) that bees will commence work in the second super as readily if put on top as under the first. I gave the readers of *GLEANINGS* the benefit (if any) of my experimental labors. Now let us see if they are backed up by reason.

It is evident that the heat escaping from the brood-chamber will accumulate in the top of the hive, and that the wax-workers require this heat most; and, again, that most wax work is wanted in the empty super. Therefore if Dr. M. has as good reasons for creating that unnatural vacuum between the surplus and brood, let him trot them out. I use starters only in the sections, and like to put a few drawn combs (extending well down to the bottom) in the center of the super. It seems to induce the bees to go upstairs sooner; but such ladders don't appear to be necessary for any but the first story, or after they have acquired the habit of going up.

I am experimenting for my own benefit; therefore when I get something good, and offer it to the public, they should make allowance for the difference in the management, location, etc., and not expect to reap large benefits without testing the plan for themselves. For example, in this case of tiering up, most if not all producers of comb honey have a horizontal bee-space between every super. I have gradually discarded until that between surplus and

brood-frames is all that I can tolerate. Those horizontal loading-halls undoubtedly hinder, and may be the sole cause of their halting between two opinions until necessity or the bee-keeper (by putting the partly filled super on top) compels the bees to reach up overhead and draw themselves through those imported spaces.

There, now, I've given Dr. Miller another chance to say, "All the same, I want a bee-space between the supers," and probably a majority of bee-keepers will always tolerate the nuisance because of some advantages, and also trouble of making the change in the surplus-arrangements. But the specialist, who manipulates not for pleasure, but for the money there is in it, will shut down on those promenade-halls, and keep his bees inside of the sections, where they will be useful, instead of scrubbing and daubing the top of every section. If those who do not enjoy lifting supers off and on again, and those ready to crawl out of that horizontal rut are of sufficient number to warrant space for a description in GLEANINGS, I will explain how they can test the principle, with but little expense or labor.

Savanna, Ill.

[Dr. Miller replies:]

WHY THE EMPTY SUPER SHOULD BE PUT UNDER; THE PHILOSOPHY OF HEAT RISING, ETC.

In the first place, friend Handel, I don't lift *heavy* supers off the hive and on again. They're only about half full, and weigh somewhere in the neighborhood of 15 pounds. But I suspect there isn't as much difference in the amount of strength laid out as you suppose, between your way and mine. Let us compare.

Suppose on the same date you and I have each a hive on which there is a super half filled, ready for an empty super to be added. I go to mine, lift off the half-filled super, put on the empty one, then lift back the half-filled super. You simply put the empty super on top, without touching the half-filled one. Now we'll go again when the first super is ready to take off, the second one being about half full. You lift off the half-filled super, take off the full one, then put back the half-filled one. I take off the full one without touching the half-filled one. So you see the labor exactly balances. You do the extra lifting one time, and I do it the other. That's on the supposition that we know, without looking, just when the full one is ready to take off. As a matter of actual fact, we don't know when the full one is ready to take off, and a good many times look at it only to find it not yet ready. At such times you have to lift off the partly filled one and then lift it back, whereas I have no lifting to do. That makes my way appear to have less lifting than yours, doesn't it?

So my answer to your question, why I waste my strength "lifting heavy supers off the hive

and on again," is because I don't know any other way that takes so little lifting.

You have proven to your satisfaction that bees commence work just as readily in the second super if it be placed on top as if placed under. Others have proved equally to their satisfaction that bees will commence always as readily, and generally more readily, in a super placed under. So the only thing is for one to practice one way and the other to practice the other way. Only the beginner, until he has had experience of his own, will do well to follow the practice that has been found best by almost all, for, as you say, almost all raise the partly finished super and put the empty one under.

You want me to trot out my reasons for creating that unnatural vacuum between the surplus and the brood, if I have any "as good" as yours. All right; I'll produce the best trotting stock I have. But, first, suppose we take a look at the teeth of your trotters. "The heat escaping from the brood-chamber will accumulate in the top of the hive," and so the wax-workers, which need heat, ought to be there. Granted that heat rises, does it accumulate? Right by where I am now sitting is a small register which lets the heat up from a fire below. When the register is open, allowing the hot air to rise through it, the metal becomes so hot it burns my fingers. Now close the register and let the heat "accumulate." Does the metal get red hot? On the contrary, it becomes quite cool to the touch. Don't take things for granted, but "prove all things," and then you'll not think the second super is warmer than the one under it. Heat rises from a stove, and it's warmer at the ceiling than down at the floor; but hold your hand directly over the stove at the ceiling, then lower it, and you'll find the heat becoming greater the nearer you approach its source. So, the nearer the brood-nest (the source of the heat) the warmer you will find it. All the heat that's in that upper super must come up through the under one; or, to put it another way, the upper super gets its heat from the one below it, and it is not likely to be warmer than the one from which it gets its heat.

Now as to that "vacuum" business. My reason "for creating that unnatural vacuum" is that bees, like Nature, "abhor a vacuum," *provided* the vacuum be between two parts of their work. So when the vacuum is "created" they hustle to get it filled up. But how much less vacuum do you have than I? When an empty super is put on, isn't there just the same vacuum in it whether it be over or under the previous one?—only create your vacuum outside of the space occupied by the bees, and they'll not go up for the sake of filling the vacuum, but simply and solely because they are crowded for room. With your plan the bees leave home and friends to commence in a new spot at the top of an empty super; whereas

with my plan they commence work right under and close to the bees at work above them.

And just that difference between commencing promptly in the second super, or waiting to be crowded to it, may make the difference between filling up the second super and swarming. The thing desired is to get them at work promptly on as large a surface as they will profitably occupy, and yet not have them commence work on more than they will finish up in good shape. If they commence work on five supers, and have material enough to fill only three, we may expect a large proportion of unfinished sections, if, indeed, any of them are finished. But equally we'll have unfinished sections with only one super on, provided there is not honey enough to fill it. The bee-keeper must use judgment, in an ordinary season getting the bees to occupy a goodly number of sections early in the harvest, and crowding as much as possible toward the last.

That bee-space between supers, to which you object, is in some respects objectionable, but nearly every one submits to it rather than submit to something worse. At different times it has been discarded, only to be taken up again after trying some other way. A quarter-inch space between two supers is a bad thing; but no space at all is still worse, I think, in the judgment of those who have thoroughly tried both ways. But if you like to have one super jammed down on another, to be glued together by the bees, with the chance of mashing bees between the two, there's no law in Illinois to prevent it.

Marengo, Ill.

HONEY AS A DIET.

WHY IT IS NOT EATEN MORE; HOW TO DEVELOP THE HOME MARKET; IS GRANULATED SUGAR ADULTERATED?

By C. Davenport.

I was interested in reading your article, "Honey as a Diet," page 92; but I disagree with you on some things. First, you say we have a good deal of prejudice or distaste for honey, real or fancied, to overcome. I have sold a good deal of honey, and it has been seldom that I found any prejudice or distaste against it; and when I have, generally it was caused on account of their having had some poor or inferior honey before. A good many bee-keepers, instead of doing any thing to increase the sale of honey, are doing more to injure it. These are mostly the ones who do not take a bee-paper, and you can not get them to subscribe for one, because they know all about the business. With them, any thing gathered by the bees is honey, and is sold for what they can get; and if they can't sell it all in the fall, most of them will put it in the cellar, where it often becomes sour, and even

moldy. It is then put on the market in the spring; and the consumer who buys a few pounds of this is not very anxious for any more. But with a very few more seasons such as we have had for the last three or four years, this class of bee-keepers will be pretty well done away with around here, and I think in many other localities as well.

Again, you say that many persons do not like honey. Of course, there are some who do not; but in all of my experience I have found but very few who did like good honey. I have found quite a number of persons who liked it, but could not eat it, as it did not agree with them. In regard to the family you have mentioned, who are able to have most of the luxuries on their table that can be bought, but seldom use honey, I wish there were a good many such families around here. There used to be a good many such here, but most of them are now my best customers. Let me describe one case.

A few years ago I went into the store of a prominent merchant in a neighboring town, and asked him if he used honey. He said he did not. They used to sell it in the store, but it was always dripping and daubing every thing up, and he did not want any thing more to do with it. He did not like it himself, and none of his family cared much about it. I told him I should like to have him try some of *my* honey. He asked me how I sold it. When I told him 17 cents a section that would weigh nearly a pound, he said he could buy all the honey he wanted, for a shilling a pound. I then asked him if he bought butter, and what he paid a pound for it. He said butter was worth from 10 to 20 cents per pound, according to what it was.

"Well, Mr. W.," said I, "there is as much or more difference in honey than there is in butter. Now, I am going to leave you a case of honey; you try one of the sections, and if you do not like it, it will not cost you any thing. I will be around again in two or three weeks, and will take away what you have not used or do not want."

This was white-clover honey, and it was very nice. It was packed in cases that held 24 sections. When I saw Mr. W. again he asked me if I had any more honey like that I had left before. On my replying in the affirmative he said he would like two more cases just like the first one. He has bought three cases of me each year since. He has quite a large family, and is well able to pay for what they like.

Of course, some years we do not get much clover honey, and some seasons we get none at all; but there are other kinds that are good, such as basswood, goldenrod, aster, etc.; and I find many people who prefer some of these kinds to clover honey; and if one works up a large home trade, and secures 100 or more regular customers, he can dispose of a good deal of

honey, and realize much more from it than by shipping it to large city markets; and in my opinion there is no better way to increase the use of honey than for each of us to thoroughly develop our home market. It may surprise you when I tell you that I have some regular customers, private families, who buy over 100 lbs. each year; but I have a number of such, and expect to keep them in spite of the fact that sugar and syrups are cheap.

ADULTERATIONS IN SUGAR.

The truth of the matter is, molasses and syrups of all kinds, at least such as we get here, are adulterated so that they are not fit to use, and most of the people around here have found it out. Here we can also buy a large pailful of jelly for a few cents. I do not think such things injure the sale of honey much if any; for after one has eaten such stuff a short time he prefers to buy honey, even if it does cost more. Most if not quite all kinds of sugar are adulterated. Almost every one seems to think that granulated sugar is pure, and that granulated sugar is always alike. As you undoubtedly know, there are various kinds or brands of granulated sugar; and while I have no doubt that they are all adulterated, I know some kinds are more so than others.

Now, I do not think that I have ever seen any honey on the table at a hotel; but I do not think this is because it would not be eaten if it were there. Last fall I took the train one day and went to a near town where I sold some honey by sample. I sold one 24-lb. case to a hotel-keeper; and when I delivered it I went into the office with it, where the proprietor and a number of his boarders were. I started to tell him I had brought the honey he had ordered; but he did not let me finish. He hurried me right through into a private room with it. I do not think he wanted his boarders to know that he had bought any honey. Very likely this was not put on the public table. But if it was, I have no doubt it was eaten in preference to molasses or syrup.

Southern, Minn.

[The article on page 92, calling forth this, was not written by me; but as no name of any kind was attached to it, Mr. Davenport very properly thought it was written by one of the editors. The name, a *nom de plume*, was left off by oversight. It should have been credited to "Novice."

This matter of developing a home market is a good one; and our correspondent's scheme, while by no means a new one, of leaving a fancy article to sell on its merits, is most excellent.

As to adulterations in sugar: We have been taught for years that granulated sugar could not be successfully counterfeited, and that, therefore, it was always pure. From time to time, reports from the Chief Chemist, at Washington, showing an analysis of the foods commonly adulterated, have come into my hands; but among the long lists therein I do not remember to have seen granulated sugar. I think our correspondent is mistaken in thinking it is ever adulterated. The brown sugars

may be and probably are adulterated more or less. I wish some expert on sugars would enlighten us on these points. See Editorial.—Ed.]

PROFITS IN THE GROWING OF ALSIKE.

HOW 30 ACRES YIELDED OVER \$1000.

By Frank Coverdale.

Mr. Editor:—It appears to me that more should be known about the cultivation and growing of alsike clover for profit. My eight years' experience with it has most decidedly prompted me to raise more each coming year.

I first began sowing it with red clover and with timothy, and afterward by itself, which has proven more profitable than any grass or grain crop on the farm. Perhaps some one might say, "How do you know?" I answer, "Because I have kept an account, and know whereof I speak."

One year I cut and thrashed 8 acres. It yielded 4 bushels per acre, and it sold for \$10.00 per bushel, and the net value was close to \$40.00 an acre for the ground on which it grew. To be sure, clover seed was high that year.

Now I wish to tell the readers of GLEANINGS what the income of 30 acres of alsike will do for me this season. I cut it when the seed was ripe, stacked it up nicely, and green as tea leaves; hulled it, and got 90 bushels of nice seed. It yielded 4 stacks of good hay, or about 40 tons, this very dry season. It is all fed to the cattle at this date; 72 of 1080 steers lived from the beginning of winter with nothing else in the way of hay up till about Feb. 1—nearly half the winter. With the above was fed each day 8 bushels of corn, and the steers look fat and plump; in fact, I feel really enthusiastic over the matter; and a better aftermath I never saw grow.

Now let us count the profit: 90 bushels of seed, we will say, will net at least \$540.00; 40 tons of good hay, \$240.00, or a total of \$780.00, saying nothing of the after-growth—\$26.00 per acre at least—a far better showing than the average cornfield, even when corn is selling at 40 to 50 cts. per bushel. The clover has left the ground in the best possible shape to grow corn or any other cereal that grows here.

Now, kind friends, I have told you how it has profited as a stock-raiser; but let me tell you that, had it not been for the alsike bloom this last season I could not have sold \$250.00 worth of honey. So it will be proper to add the above profit from honey to the proceeds of alsike, which would count up to \$1030. Can another do likewise? I would most assuredly say yes; but, let me add, try all new things on a limited scale, and hold fast to that which is good.

Delmar, Iowa, Feb. 9.

[Farmers are complaining of the low prices of the ordinary produce. Let some of them

turn their attention to alsike. It is hardly probable that all will do as well as for friend Coverdale; but the experiment, at least on a limited scale, will be worth the trial.—ED.]

HOW I MET A. I. ROOT IN THE PINE WOODS OF FLORIDA.

"WE MET BY CHANCE," BUT NOT "THE USUAL WAY."

By Thaddeus Smith.

I first became acquainted with the name and writings of A. I. Root some 25 years ago, when he was a correspondent of the old *American Bee Journal*, then published in Washington, D. C., and wrote over the *nom de plume* of "Novice." This was before GLEANINGS was probably ever thought of, and before A. I. R. had any idea of going into the manufacturing of bee-keepers' supplies. Being very much interested in Novice's letters I found out his true name and address, and had a short correspondence with him. When the publication of GLEANINGS commenced I became one of the first subscribers, and an occasional contributor; and, having read GLEANINGS ever since, and being personally interested in the subjects its editor treated—bee-keeping, gardening, morality—it was but natural that I should become personally interested in its editor and his work and his family; and yet in all these years we had never met face to face. It has long been my desire to visit the Home of the Honey-bee, that I might become personally acquainted with the Roots and their associates, and see their interesting establishment. It is not very far from my home on Pelee Island, in Lake Erie, to Medina; but something has always been in the way of my getting started there.

In November last I left my island home to spend the winter in Kentucky and Florida. I saw in GLEANINGS that A. I. R. was also going to Florida. He was to start earlier than I intended, and he intimated that he would go on to Cuba, so I had no expectations of meeting him. I started for Florida Jan. 22d; but before I started I copied from GLEANINGS the names and addresses of several Florida correspondents. I had no special business with these bee-keepers; but I thought that, if I should go near them, I would call, as I generally find them congenial companions. Among these names was that of Charles Norman, of St. Petersburg.

I spent three weeks on the east coast, from Jacksonville to Palm Beach on Lake Worth. I then made my way across the State to Tampa, my objective point being Tarpon Springs, where I had an engagement to meet some Kentucky friends. To get from Tampa to Tarpon Springs, it was necessary to cross the bay to St. Petersburg to get to the railroad, and then I had six hours to wait for the train. To pass

the time, and see if there was any thing there of interest, I took a walk with my daughter, who is traveling with me; and as we passed the postoffice I said to her that I knew of a bee-man living there, and I would inquire for him. "Yes, I know Mr. Charles Norman," the young man said. "He lives ten miles out in the country."

Seeing a livery-stable on the opposite side of the street I crossed over and asked about Mr. Norman. I was informed that they had just sent a man out to Mr. Norman's. It was only seven miles, and he would take me out for two dollars. I did not think that I wanted to see Mr. Norman quite that bad, but felt curious to know who the man was that had just gone to Mr. Norman's, and concluded it must be some bee-man with whose name I might be familiar, and I went back to the hotel to consult the register. To my surprise and delight I there found the names "A. I. Root and daughter." The clerk said the gentleman had gone out, but the lady was in the house. I told my daughter, and sent her upstairs to hunt up Miss Root, and she brought Miss Constance down, and we very soon became acquainted. Didn't I know her as "Blue Eyes" when she was a laughing, romping child? know her as a college student? know her as the musical genius who handled the violin and the bow? know her as the business young lady, the stenographer and "pretty typewriter"? Of course, I did; but we had never met before, and there she now stood, looking just as I expected to see her—blue eyes still. She said it was doubtful about her father coming back that night. My only chance, then, of seeing A. I. R. was to follow him up, and I hurried back to the stable and got a rig as soon as possible, and struck out upon a "trail" (they have no roads in Florida), through an uninhabited pine forest, for Norman's. When we had gone some six or seven miles we met the other buggy returning. I had seen some pictures of A. I. R., and had so often in fancy pictured him in my mind that I flattered myself I should know him wherever we might meet. But the little thin-visaged man, with short gray (nearly white) beard, with a brimless *fur cap* on (down here in Florida), and his coat buttoned up tight around his throat—this man whom I was meeting, sitting in a buggy by the side of a broad-faced colored boy—did he look any thing like the A. I. R. whom I expected to meet? Not much. But as my driver said that he was the man he had sent out to Norman's, it could be no one else. I jumped out of my buggy, and stepped forward to greet him. I asked if he did not know me. I knew, of course, that he did not, for we had never met before. When I handed him my card, the name seemed familiar to him, and I invited his colored driver to get out and give me his place. As we drove through the lonely pine woods back to St. Petersburg, you may be sure I had a visit with

him that I greatly enjoyed, and shall never forget.

But our ways diverged, and the time for separation soon arrived. Miss Constance was not going with her father, but would go on the same train with me to Tarpon Springs, where I had expected to meet her and have the pleasure of getting better acquainted with her, and of introducing her to a number of my friends; but when I went to look her up next morning I found that she had left the place.

THE ANDERSON SWARM-HIVER.

By Louis Anderson.

In the spring, or before the swarming season, prepare a hive-stand large enough to hold two Dovetailed hives placed side by side, and two inches apart. Place the colony of bees upon the left end of the stand, and an empty hive on the right (the bee-keeper is supposed to be standing in front of and facing the hive.)

As the swarming season approaches (say from the first to the tenth of May), reverse the hives, placing the empty hive on the left and the colony on the right, taking care to have the front of the hives on a line with each other, and about two inches apart; then set the swarm-hiver upon the alighting-boards and fasten with a screw through the blocks on each end of the hiver, and screw up tight. If the hives stand upon a line, there will now be no

outlet for the bees except through the hiver. Now close the entrance to the empty hive by placing a wood strip large enough for the purpose against the entrance upon the inside of the hive, to keep the bees out until they have become accustomed to the hiver, which will be after the first day. As soon as they have become accustomed to the hiver, remove the strip and put in frames of empty comb or foundation, and the hive is ready for swarms. A small alighting-board should be placed from the entrance to the ground, for the bees to alight upon. If the hives are placed well to

the front of the hive-stand when first placed, and well to the rear when reversed, the entrance to the hiver will be very near where the entrance to the colony was before the hives were changed.

OPERATION OF THE SWARM-HIVER.

When the swarm issues, the bees and queens pass out of the chamber in the hiver in front of the colony through the perforated zinc and the wire-cloth cones, into the chamber in front of the empty hive, and the queen is there trapped. The swarm, upon discovering the absence of the queen, returns to the hive, and, finding the queen at the entrance of the hiver, which, being directly in front of and communicating with the empty hive, the bees at once enter the empty hive with the queen, and commence work. The hiver may now be removed by taking out the two screws, and all queen-cells except one cut out of the parent hive.

The swarm may be strengthened, if desired, by removing the hiver in the middle of the day, when the bees are flying freely; the entrance to the hiver being in front of the swarm-hive after the hiver is removed, the field-bees will return to the swarm-hive. If the swarm is considered to be strong enough, the hiver should be removed early in the morning, before the bees are flying.

WHAT IS CLAIMED FOR THE ANDERSON SWARM-HIVER.

1. It will hive large full swarms.
2. To see if the bees have swarmed, it is only necessary to raise the cover to the empty (or swarm) hive.
3. Either of the hives may be examined without disturbing the other.
4. If a second swarm issues before the hiver is removed, it will be hived with the first swarm; in such case the old (or laying) queen will be accepted by both swarms, and the young queen balled and destroyed.
5. If the bees do not swarm, the colony gathers honey just as well as without the hiver. During the season of 1892 the colony that made the most comb honey in my apiary of 40 colonies had a hiver attached, but did not swarm.
6. If drones clog the entrance to the hiver, the perforated zinc slide may be withdrawn, the drones liberated, and the slide returned; the drones may then be destroyed, in the evening, at the entrance of the hiver. Or make a small box, three inches high, the size of the entrance to the hiver, but without top or bottom. For a top, nail on a strip of perforated zinc; and in place of a bottom, make a tin slide to work the same as the perforated zinc slide in the hiver. To clear the hiver of drones, withdraw the tin slide from the box and place the opening in front of the entrance to the hiver. Now remove the slide in the hiver, and the drones will enter the box. As soon as the drones are in the box, return the tin slide and remove the box, and replace the zinc slide in

the hiver. The drones are now all prisoners in the box. As soon as the worker bees that have been caught with the drones have escaped through the perforated zinc top, shake the box pretty hard for a few moments, which will stun the drones, then withdraw the tin slide and empty the box on the ground, where the drones may be killed by tramping them with the foot.

THE ANDERSON SWARM-HIVER AS USED IN THE PRODUCTION OF COMB HONEY.

For the production of comb honey I have found no better method than the following:

After putting on the swarm-hiver I place four frames filled with sheets of foundation in the empty hive. The fourth or fifth day after the bees have swarmed, the swarm will have settled down to work, and will have the foundation in the four frames well drawn out. I then in the middle of the day, while the bees are flying freely, take four frames of hatching brood, with the adhering bees, out of the parent hive, removing all queen-cells if there are any on them, and place two of the frames on each side of the four frames of foundation in the swarm hive. I then take the half-story with the sections and bees off the parent hive and place it on the swarm-hive; then remove the hiver, and move the parent hive with the four remaining frames of brood to a new location.

All the field-bees from the parent hive will now return to the swarm-hive, which, with the four frames of hatching brood taken from the parent hive, will make the swarm very strong; and the swarming fever having been satisfied, work will go right along in the sections. When the next colony swarms I proceed in the same manner and place the parent hive, when removed, by the side of the parent colony that cast the first swarm. As soon as the first parent hive has a laying queen I remove the queen from the other hive, if they have one, and then double the two together by placing the frames from each hive alternately in the same hive. I then put on a super full of sections, and if honey is coming in freely the bees will enter the sections at once. By this method the increase is kept down to one colony for every two swarms. If increase of colonies is desired, instead of doubling the parent hives put in each parent hive four frames of comb or foundation, and allow them to build up.

By the above method there will be no second swarms, as the removal of the four frames of brood and bees, and the loss of the field-bees, so weakens the parent hive that, as soon as the first queen hatches, the remaining queen-cells are destroyed.

[After friend Anderson had sent the foregoing, he later sent the following, with another drawing showing the arrangement somewhat simplified. We have had it also engraved.—Ed.]

Within the past two days I have thought of

a slight improvement in it, as will appear in the drawing which I inclose herewith. You will notice I have cut off the corner of the chamber in front of the colony, and beveled the hive, thus doing away with a useless vacant

space—making the hive less bulky, and considerably decreasing the amount of lumber required to make it. When made as shown in the drawing, a $\frac{1}{4}$ -inch board 10 in. longer than the top board of the hive sent you, cut diagonally, will make both top and bottom of the hive, and no end board is required in the beveled end, as the front board nails up to the block in the end of the hive.

Bloomsbury, N. J.

THE DANZENBAKER HIVE AND SECTION.

By F. Danzenbaker.

Forty years ago I managed bees in box hives, and then progressed to the Quinby and American hives, with large and deep brood-chambers and combs, liable to stretch, sag, and bulge, when heavy with honey. The care of keeping the hives exactly level to secure nice straight combs true in the frames led me then to desire a shallow comb-frame, more than 25 years ago, which I laid aside when the Simplicity hive came in vogue, that I might be in fashion with those using the standard hive and $4\frac{1}{4} \times 4\frac{1}{4}$ section, the production of comb honey being my specialty; and during that time I have been a close observer of others, testing what I thought desirable improvements, including the open and closed end frames and the Hoffman deep top-bars, etc. However, I am chiefly indebted to the champion comb-honey producer, Capt. J. E. Hetherington, of Cherry Valley, N. Y. (who has raised 40 tons of comb honey in a year), from whom I learned the superiority of the oblong deep honey-sections as used by him and others in New York and the East. Twenty-five per cent more of them will stand on a given hive surface than the standard $4\frac{1}{4} \times 4\frac{1}{4}$ sections; and this form conveys a better impression of full weights. Having space for a deeper cluster, the bees enter them more readily; and, filling them out better at the sides, they are safer in transportation; more attractive in appearance, they sell for two cents each more in market. Thirty-two of these deep sections, in a case, require no more hive surface than 24 $4\frac{1}{4} \times 4\frac{1}{4}$ sections on the eight-frame Dovetailed

or any other hive. They are scored out *at the corners*, providing side openings for free passage of air and bees between the tiers of sections, also saving the irksome labor of scraping propolis from the corners of sections; said corner being cut away, the bees do not daub or glue the openings which they can pass through. The sections are nicely filled at the corners, and are ready to set right into the shipping-cases, as taken from the supers.

The Root style of section-holder (put together by dovetailing) is made to hold four of these sections, there being eight holders for each case, supported within the metal hangers and case, provided with wood separators nailed to them to make the sections of uniform size and weight.

The entire case of sections and holders is covered air-tight with a layer of paraffine paper, which the bees do not cut away if covered over with other paper or cloth, and held down close and smooth by thin boards beneath the outer cover. This is of the utmost importance, as bees can not work to advantage until the top of their hive is *air-tight* to retain the warmth of the colony, provided there is abundant ventilation at the entrance of the hive, which may be controlled to suit the seasons and conditions of the colony, to restrain the swarming impulse. When extra stories are used, and more ventilation is needed, it can be given by reversing the bottom and shifting the first or second story forward, thus giving full and direct ventilation at front and rear if desired, which will cause the bees to store their honey at the top of the hive, instinctively to avoid danger from robbers.

The hive-bottom is made to give a deep space and opening under the frames by reversing it when desired to admit more light and air to force the bees to store their surplus at the top of the hive. The bodies and supers are all alike, square edged, to fit tightly together for tiering up, consisting of but two pieces, ends and sides dovetailed to go together the same as four-piece sections.

The brood-frames are made in the same way; but the ends and top and bottom bars being alike there are but two kinds of pieces used in them. The section-holders are also made of two pieces, so in each of the separate parts of the hive they duplicate each other, to have the fewest separate pieces possible; and as all are made for me by the A. I. Root Co. with the latest improved all-iron machinery, the work is as nearly perfect as possible to be, and is very easily put together.

The hive proper consists of two stories used as a brood-chamber, and one story for a super; extra supers can be ordered to use if two tiers are needed. Two stories are intended to be used in wintering, as well as breeding up in spring, as the full bee-space is at the top of each case, independent of the others. The lower hive is intended to be placed at the top in

putting on a super to bring the brood directly beneath the sections, which stimulates the bees to storing honey directly above it; by alternating the bodies at proper intervals, the uncapped honey will be carried from the lower one to give room for the queen; and the two stories giving ample room for a brood-chamber, no queen-excluder is needed where separators are used between sections filled with worked foundation, as the queen will not leave a large brood-nest for single sections, except to raise drones when not allowed drone comb in the brood.

METAL HANGER.

The brood-frames for sections, and the brood-frames, are supported in the case on a removable sheet metal provided with turned edges or flanges on alternate sides, to hang upon the top edges of the cases, with the end-bars of brood-frames or section-bars resting upon its lower edge, this unshrinkable metal having such

bee-space that *will not* be contracted by shrinkage above the brood-frame and sections as may be desired, and determined by the width of the sheet metal and corresponding depth of the cases. These metal supports are adapted to either deep or shallow hives, using close-fitting end-barred brood-frames. This arrangement gives increased capacity and facility of manipulation, as these removable supports *can not* be glued fast to the hive, and are fully covered by the end-bars of the frames, which they support and protect from touching the end of the cases, so that the bees *can not* glue the frames fast to these supports, *nor* to the sides of the hive, and they are easily removed with the brood-frames or sections by reversing the case and lifting it off, or they may be pressed down over a follower the same as a "T super," leaving the sections or frames free for removal or inspection. Paper or other elastic material may be placed between these supports and the cases to form a cushion giving flexibility, if de-

sired, to facilitate the nlling and removal of frames or sections.

Washington, D. C.

FLORIDA MOSS AND HONEY-PLANTS.

By Mrs. L. Harrison.

I read with much pleasure A. I. Root's notes of travel in Florida. For four seasons it has been my winter home. This winter is very materially different from previous ones that I've known, for frost has robbed the orange and lemon trees of their shiny green leaves, and kept the roses from blooming. Whenever I pass under the magnificent live-oaks, hung with nature's drapery, I feel like raising my hands in adoration to the Giver of all good, with an invocation that this great work of his, for centuries, may not be rudely destroyed. "The groves were God's first temples."

The botanies class Spanish moss as an air-plant, and I fail to find any roots that would indicate that it is a parasite; but it is said in time to kill trees. To-day I passed through a grove of live-oaks, and I noticed several great trees, heavily laden with this moss, that were entirely dead. If it is a parasite, it draws life from both living and dead trees—from the sap of the living and from the decaying wood of the dead. I think it is a mistake, that it will grow hung on a wire. Many observing persons think that its presence indicates malaria, and, by a wise provision of nature, absorbs it in some way. It evidently thrives best where the fogs are the thickest and most frequent, holding moisture in its meshes. It does not grow naturally on our own grounds; but when I put it upon the limbs of scrub oaks it lives, but does not thrive as it does in its native habitat. I grow it as food for my fowls, for they are very fond of it; so are cattle; and I wonder why the residents do not pull it down for them, when forage is so scarce that they will eat daggers. I've not been able to learn whether bees work upon this moss while it is in bloom.

If this moss is gathered and put into pillows and mattresses in its green state it will soon smell very offensive. The parasite must be killed by burying in the ground, or by boiling, before it can be utilized in this way, when it will make good mattresses and pillows.

The ti-ti is an excellent honey-plant, and should be spelled with a hyphen. It may be found in a Southern botany, and is known as *Cliftonia ligustrina*. It is an Indian word, and means tangle, or thicket. The name is given to the small trees; also the places where it grows are known as ti-ties. It grows only in

living water; and if the water is dammed up, and becomes stagnant, it will perish. The bloom is small and white, growing in racemes, and is sweet and fragrant, yielding honey that is white and of good flavor. It had commenced to bloom before the great Valentine storm of snow and sleet, which put an end to it; but it is again opening, Feb. 25. It is much used for decorations at Eastertide.

I see that you class goldenrod as blooming here in September; it may bloom then, but I've seen bouquets of it gathered in April.

You should not fail, while in Florida, to visit the largest apiaries in the State, of Alderman and Roberts, located at Wewahitchka. This is an Indian name, meaning the "lakes of the two eyes," or eye-glasses, as they are shaped like them, and are about 35 miles long and 18 miles wide—otherwise known as the Dead Lakes. They are thickly studded with dead cypress-trees. One of the most weird experiences of my life was while returning from visiting an apiary located on an island. It was in the gloaming; and the approaching darkness, as I sat in the canoe, with the tall cypress-trees bearing upon their branches a heavy drapery of moss, and only the strong arms of a trusty colored man to guide and propel the little craft through the intricacies, was a scene long to be remembered.

The trade-mark of this firm is "Orange Bloom." Their surplus honey is not gathered from this source, as that from the orange is used in rearing brood. There are many groves in this locality. The surplus honey is gathered from tupelo. There are several varieties, known as black-gum, sour-gum, and gum-trees. Bees also gather honey from moonflower, an aquatic vine. This region will support more colonies than any other I ever saw; but it has its drawback, in being very malarious.

St. Andrews Bay, Fla., Feb. 26.

WHEN TO TRANSFER BEES.

Question.—Having quite a number of colonies of bees in box hives which I wish to transfer, I should like to know when this can be done to the best advantage. Can I do it as soon as spring opens? or had I better wait till the bees are securing honey from the fields?

Answer.—The transferring of bees from box hives, or "gums," or from one style of frame hive to another, can be successfully done at any time of the year when bees can fly, if the operator understands just the needs of the case; and I always look with pride on that man or woman who has ability enough to accomplish any thing successfully which it is necessary to

do at a certain time, no matter whether said time is the most propitious or the most unpropitious. The one who can set out a row of small-fruit plants, and make all live in a time of extreme drouth in midsummer, or the person who can successfully transfer a colony of bees in early spring, when robber-bees are prowling around, is to be admired; yet unless there is some urgent reason why a certain thing should be done at a certain time, it is always best to wait about doing any thing till that time when every thing is the most conducive toward a successful outcome. As I consider it, there are two seasons of the year when bees can be transferred to the best advantage, the first being during fruit-bloom, and the other 21 days after a prime swarm has issued. During the first part of fruit-bloom the scramble after new honey is such that one is not liable to be annoyed with robber-bees, and at this time there is very little honey in the combs to cut through and make a sticky mess of every thing which is used during the operation. Again, as the bees are getting their first honey they are eager for something to do inside the hive at night, hence will repair all the mutilations of comb, fasten the same in the frames, etc., much more readily than at any other time. With all the above being true, fruit-bloom brings the most auspicious time for transferring bees, but it has this drawback: As a rule, the bees have got under good headway rearing brood, and we shall find the combs half or two-thirds filled with the same, so that, in cutting them to fit our frames, much brood must be sacrificed, as well as displaced in the brood-nest, owing to our not being able to secure all in the shape in the new hive which it was in the old one. All of this has a tendency toward a loss of bees; and as all of the brood which is sacrificed at this time would become bees of the right age to do the best labor in the honey-harvest, had we left the transferring till later on, we can see that a loss must be made by doing our transferring at this time of the year, with all colonies except those which have little brood in their combs. For this reason I prefer to wait till 21 days after the prime swarm went out. At this time all of the brood will have hatched from the combs, except perhaps a few drones, and the young queen will have laid but a few days, not long enough so that there will be much but eggs in the combs, so that all we have in our way now is the honey which the combs may contain. As this comes at a time of year when the bees are securing all of the honey they want, and the weather is always warm so that no brood or bees will become chilled, we can now do our work right out in the bee-yard, this making it more convenient. Then should you desire to use the Heddon, or modern plan of transferring, by driving out the bees and hiving them in a hive filled with comb foundation, this is just the time to do it,

for the combs are free of brood, so only the one operation is needed, and the old combs can be cut out at once and placed in the solar wax-extractor, doing this work right beside the wax-extractor, so that in an hour or two you can have both the honey and wax in shape to use, thus saving time and delay which would result at any other time of the year.

HOW MUCH FOUNDATION SHOULD BE USED IN SECTIONS?

Question.—As I wish soon to prepare my sections for the coming honey-harvest, I should like to know just how much thin comb foundation it is best to put in each one. Shall I put in just a small triangular starter, or fill the section full?

Answer.—The answer to this question will depend quite largely on two things. The first and most important is, have we the necessary means to procure all the foundation which will be needed to fill our sections, without depriving ourselves or family of some of the necessities or comforts of life? If we have not, then my way would be to use triangular starters, the same having each of the three sides about two inches long, in three-fourths of the sections I was to use; and when the season opens, put in starters of white new comb, which it is always easy to find or produce during fruit-bloom in any apiary, in the remaining sections. In this way little if any difference as to the yield of honey will be seen in an ordinarily good season, especially if the sections containing the starters of comb are scattered uniformly among those having the foundation starters. The difference when so working will be that the sections will not contain all worker comb, nor present quite so fine an appearance, nor the combs be attached to the wood of the sections all around quite so well, as where the foundation in full sheets is used; still, very little difference will be made in the selling price for the lack of the full sheets of foundation.

Again, if I thought it best to hive my new swarms on frames filled with comb foundation, so that wired frames filled with worker combs would be a certain result, then I would use only starters in the sections as above. When a prime swarm issues, they go forth, as a rule, with wax already secreted in their wax-pockets, so that they may at once commence to build combs in their new home; and if the new home is already supplied with all the necessary combs this wax is wasted, or, what is often the case, worse than wasted, it being added to the foundation already in the sections, so that, instead of drawing out the side walls of the foundation, they build with their own wax the cells of the combs, thus leaving the foundation in the sections the same as it left the mill. This causes the grumbling about "fishbone" in section honey, which we often hear about. Now, where I hive swarms on full combs, or frames filled with foundation, I use only start-

ers in the sections, and find that the bees will build the combs in the sections while they are drawing out the foundation below, and thus a saving is made. But as a rule I prefer to fill the sections with foundation, that I may have handsome salable sections of honey, and use only starters of foundation in the frames below, having the starters in the frames, say from one to 1½ inches wide. By contracting the brood-chamber to six frames, the bees go to work at once in the sections, drawing out the foundation there, while at the same time they build all nice straight worker comb in the frames, which does not detract from the amount of section honey in the least, so far as I can see.

THE CROSSES OF FIVE-BANDERS.

I notice in January 1st GLEANINGS, page 23, an editorial stating that a cross between a queen of five-banded stock and a black drone, or a five-banded drone and a black queen, will, according to your experience, result in all the bees showing at least three yellow bands. Now, there must certainly be a mistake somewhere, as our experience has been to the contrary; for we have had many a fine golden five-banded queen mated to a black drone, which in every case produced from the finest five-banded bees to the blackest native, and we had also the reverse. A black queen mated to a five-banded drone produced bees as black as tar, and now and then a bee that showed three, four, and five bands. LEININGER BROS.

Ft. Jennings, O., Feb. 6.

COUNT YOUR MONEY OVER.

When I was selling my honey this fall, the last I sold came to about \$30.00. It was in Detroit, and on the street. The man took it at my weights, and we reckoned the price the same, and he paid me before the honey was taken from my wagon. He took a roll of bills from his pocket, counted them, and handed them to me. I counted them, and found \$21.00. Said he, "Let me see them. I thought there was more." He counted them over again, and said, "Yes, that is right—twenty-one," handing the roll back, which I put into my pocketbook by itself. He then paid me the rest in silver, put the honey in his wagon and went his way, while I went home congratulating myself for selling out at a good price. You can imagine my feelings, when I got home and counted my money, to find his roll of bills just \$10.00 short. It made me blue for a while, I tell you, for I could ill afford the loss; but God probably knew what it was for. It is the first time I ever lost any that way, but have since learned of quite a number

doing so. I was watching the man all the time, and counted the bills at the same time he did. He must have been very expert at his trade. The moral it taught me is, always recount your money when it has been taken from you for recounting and handed back to you.

BENJAMIN PASSAGE.

Stark, Mich., Jan., 1895.

HOW TO EXTRACT THICK HONEY.

I wonder if all honey is as hard to extract as was mine last season. I left the honey on the hive till it was well ripened. The frames weighed about 7 lbs., and the honey was so thick I could not extract all of it, as it would break the combs. What was the cause? Is all honey so hard to extract, or was it the extractor? The extractor was of my own construction.

FRANK N. BLANK.

Prairie Home, Mo., Feb. 18.

[You must have some extra fine honey, for the thicker it is, the better. How shall we get it out of the combs? First store the combs in a warm—yes, hot room for a few hours. Use a reversible extractor; extract one side of the combs partially; reverse the pockets, throw out the honey, and then return to the first side and throw it all out. The combs break because the great weight of honey on the side opposite the side extracted presses upon the bottom of the cells; but by reducing this weight by a gentle turning of the handle, greater speed may be used to get the honey all out without breaking the combs. Of course, they should be wired.—ED.]

H. R. BOARDMAN'S ARTICLE AND C. A. HATCH'S COMMENTS.

Feb. 15th GLEANINGS is at hand, and I have read Boardman's article on hives with much interest, and can say "me too" to almost every line, especially on the tiering-up part. The whole article is well written, and the ideas are good. But let me call your attention to some points in the tiering-up paragraph. 1. He says it "involves some extra labor." Good! just my idea! 2. He says, "I do not expect the queen to continue laying in both hives at the same time." "I do expect, and am not often disappointed, when the queen goes above, that she will continue to work in the upper hive until it is full of brood." Just so! what we have always said; and while this is going on you are getting empty combs or combs of honey below, by the hatching of the brood. Do you see my position on this tiering-up question? Let me try once more to explain it. Plenty of room below for the queen, so she need not go above to lay, to the neglect of the combs below. 1. Because we do not want any empty combs in the hive. 2. Because if they are empty of brood, and the workers fill them with honey, it discourages storing above. See?

But, why do you claim Bro. B. on the eight-frame side? Simply because his frames count eight? He advocates nine, however; and when you figure out the comb surface of his

nine frames, $12\frac{3}{4} \times 12\frac{3}{4}$ inside measure, you have rather more comb surface than ten L. frames with $\frac{3}{8}$ -in. top-bars. The comb surface of 9 frames, $12\frac{3}{4} \times 12\frac{3}{4}$ in., is 1463+ in., and the comb surface of 10 frames $8\frac{1}{2} \times 17\frac{1}{4}$ in. (L. size with $\frac{3}{8}$ top-bar), is 1455+ in. Is that difference enough to argue about? Really, Bro. B. differs from the ten-frames in favoring closer spacing, not in number of frames. Am I right?

Ithaca, Wis.

C. A. HATCH.

EIGHT extra pages as usual.

OUR revised booklet on Bees and Fruit is now out. See Special Notices for further particulars.

REPORTS show that bees are still wintering comparatively well, considering the extremely cold winter that we have just had. We shall be sending out our statistical blanks soon.

WE have just had a delightful visit from the Hon. Geo. E. Hilton, one of our bee-keeper legislators, just from the Michigan State Assembly at Lansing. He is chairman of the Railroad Committee, and had arranged matters so as to get away a couple of days to make us a call—a pleasure he had promised himself for years back. Mr. Hilton is one of God's noblemen, and I wish more of our legislators had the same honest heart and the same earnest desire to do good to their fellows as he has. Although the opposition at the last election made a tremendous effort to defeat him, even putting up a union ticket combining three parties, he was elected by a handsome majority for the second time.

THE BEE-ESCAPE FAD AND BEE-ESCAPE INVENTORS.

It seems as if almost every mail was bringing in a bee-escape that some fellow has just invented. The ground has been so well gone over that none of them, so far as I know, contain any new idea other than that recently advanced by C. W. Dayton—the flood-gate principle combined with the going-toward-the-light idea. This combination, I believe, is new, though the two separate ideas are old.

Well, how about these fellows who are sending in their escapes? I have to write and tell them that their idea belongs to so and so, as described on such a page of GLEANINGS. One man wrote that he had an escape that would rid supers of bees in two hours' time. I somewhat doubted it, and the more so when I came to examine critically his escape. If I am correct, the most we can expect of any escape, on

the average, is to get the bees out of the super over night; and I am inclined to think that those who *think* they have something that is away ahead of the Porter, the Dayton, or some of the other well-known forms, that will do the work in a half or a sixth of the time, will find, upon further experimenting, their mistake. The bee-escape fad has assumed, within the last six months, or year, something of the nature of the reversing-frame fad of a few years ago. Our older readers will remember that almost every thing conceivable, in that line, was invented. Well, that condition of affairs is pretty nearly true of the escape. The old forms may be improved some, but that is about all we can expect.

HONEY IN HOTELS.

I BELIEVE it is a fact that hotels throughout the country seldom put honey on the table. The proprietors may be laboring under the impression that it is too expensive. But honey is something, a little of which will go a great way; and if only some means could be employed to induce the proprietors to place the article on the table, even if only once a week, it would add greatly to the sale of honey, and at the same time advertise it among a class of people who would use great quantities of it. If bee-keepers, whenever they patronize hotels, especially when in attendance at conventions, would call for honey at the table, it would be put there. Then producers should make an effort to sell to them direct. The following is an extract from a letter, that I take pleasure in giving here:

The writer was in Grand Rapids last week, and the first time he ever found a hotel that served comb honey to the guests was the Morton House. Upon questioning he found out that they served it every Friday night; and as they gave about $\frac{1}{2}$ of a pound to each one, you see they are liberal in serving it. You might mention this fact in your paper, as it might assist some of the bee-keepers to interest other hotels in using it, thereby making a larger outlet.

S. T. FISH.

Chicago, Ill., Mar. 7.

The proprietor of the Morton House ought to be congratulated. We feel sure that their patrons will appreciate the favor, even if comes only on Friday. Let more hotels follow the example.

GIVEN FOUNDATION MADE ON ROLLER MILLS.

WE have finally turned out a mill that duplicates almost exactly, in my estimation, the same article that comes from the Given press. Besides that, it has the advantage of the rolls in making a more regular sheet, and, I hope, a thinner base, and, in a given time, a larger quantity. Here is what Mr. R. L. Taylor says, to whom I sent some samples:

Friend R.—Yours of a late date, as also samples of foundation made on new style of machine, is received. The foundation is very much like the Given; looks exceedingly well, and, when properly

made for sections, I believe it will prove to be a decided improvement over the old kind. Of course, the main advantage will be in its use for sections, and for that purpose the sheets of wax must be made so even and thin that, in milling, the raised cell-walls will not be pressed on top. I shall, of course, be very anxious to test it when the honey season comes.

R. L. TAYLOR.

Lapeer, Mich., Mar. 8.

I wrote to Mr. Taylor that we would send him some of the Given rolled wax in sufficient quantity for him to test, to see whether it compared favorably with that made by the press. In the mean time, doubtless, other bee-keepers would like to try it. I am glad to say that we are now in position to furnish it at the same prices as other foundation, when called for. But you must bear in mind that it does not look like ordinary *rolled* wax. The walls are very thick, and the sheets of foundation have a rather clumsy appearance as compared with the regular article that we have been selling.

SIMPLE METHODS OF DETECTING WAX ADULTERATIONS.

In speaking of detecting impurity in beeswax, the Dadants, in our last issue, refer to the water and alcohol test. It has occurred to me that some of our readers would like to know what it is. On page 596, Vol. II., of Cheshire, we find the following:

Fresh wax melts at about 144°, but the melting-point rises 2° or so by a few months' keeping. The specific gravity of wax is nearly equal to that of water, and ranges between .960 and .965, water being 1.000. When adulterated with hard fats, its specific gravity is reduced, and on this fact Mr. Hehner has suggested an exceedingly simple test. Take a piece of undoubtedly pure beeswax, and cautiously mix alcohol (methylated spirit) with water until the wax just sinks. A piece of wax so adulterated would, in the same test-fluid, rise to the surface. The test must be applied, however, with great care, as any air-bubbles in or on the piece to be tried might lead to its being condemned unjustly.

A simple method for the detection of paraffine adulteration, though not entirely reliable, is to take a small piece of the suspected wax and chew it. If it crumbles up within seven or eight minutes in the mouth, it is probably pure wax. If paraffine is mixed with it, you can chew it longer without its crumbling, but it will not crumble quite so much. To sufficiently acquaint ourselves with paraffine mixtures, we took a small quantity of beeswax and melted with it an equal quantity of paraffine, and then tried it by all the various tests; but we were greatly surprised to see how very much like pure wax this half-and-half stuff looked; but according to the chewing test it showed the presence of paraffine; but the stuff which we spoke of in our last issue, and which we came very near accepting as pure beeswax, seemed to stand the chew test pretty well. It smelled like real wax; and in breaking a cake of it, it had the regulation granular appearance along

the line of fracture. But the wily chaps have discovered the process of mixing in paraffine of a higher melting-point, and had been "doctoring" it up in other ways so that it seemed to stand ordinary tests. But now since the chemist has declared the wax to be adulterated, we find that, according to the chew test, the wax does not crumble quite so promptly as it might.

Another method of detecting grease, besides the alcohol and water test, is in the use of chalk. Besides a greasy appearance of the cakes, if a piece of common blackboard chalk be scratched across the smooth surface the chalk will slip along without making any marks. If there is no grease present, a white mark will be made. Grease is also detected by the smell and by the character of the fracture. When a cake of such wax is broken, just how this fracture should look can be determined only by experience.

THE SUGARS OF COMMERCE PURE, AND WHY.

MR. C. DAVENPORT, on page 217, gives it as his opinion that sugars, even the best grades of cane sugars, are largely adulterated. Since his article, with my footnote, was made up, I have found Bulletin No. 13, from the United States Department of Agriculture by the Division of Chemistry. I find that several of the United States chemists analyzed 500 samples of sugars obtained in the open market, and that all were found to be pure, with the exception that a few of the lower grades contained an excess of water, which could hardly be called an adulterant. The Chief Chemist goes on to tell of the attempts that have been made to adulterate or counterfeit cane sugars, but all have ended in failure; and he says further, that the low price of cane sugar renders adulteration practically out of the question, even if it were possible. I think we may set it down as a settled fact, then, that granulated sugar—indeed, all of the white sugars—are absolutely pure. We know there are adulterations in other lines of food stuffs; but let us not make the mistake of jumping to the conclusion, without good evidence, that all foods are adulterated.

Perhaps it would be well to state that, in certain grades of *powdered* sugars, especially confectioners', will be found a small percentage of starch. But this is hardly to be regarded as an adulterant, because the sugars in question are designed for making frosting for cake, and the starch is an important element in making good frosting, if I am correct.

Another interesting fact—one that we have generally accepted as true, however—is, that the chemists say, "In general it may be said that, for a given sum, a greater quantity of saccharine matter can be purchased by taking the high-grade sugars."

They admit that *maple* sugar may be adulterated with cheaper varieties of sugar, because "at the present time the resources of chemistry

are powerless to detect such an adulteration. The sugar of the maple sap is identical in composition with that of the sugar cane, sorghum, and sugar beet. No discrimination in such cases can be made by analysis." I think, therefore, we may set it down as a fact, that, when we feed our bees syrup from white sugars, we are *sure* we are giving them the very best pure sweet, and at a price that is cheaper than any thing else on the market.

OUR POSITION IN REFERENCE TO PATENTS, AND TO DIVISIBLE BROOD-CHAMBERS.

I THINK we are misunderstood; and to correct some misapprehensions I will try to set forth our position. Years ago, A. I. R. gave expression to the following:

I am very glad indeed to note the disposition among bee-keepers, of forbearing to copy the works of each other, patent or no patent. The supply-dealer who would unhesitatingly copy something well known to be the property of another, without getting the privilege of so doing, by purchase or otherwise, would very likely lose more than he made, so strong is the disposition of our people to give honor to whom honor is due.

We believe every word of it to-day, and propose to abide by its spirit. We are paying royalty now on some four or five patents, and we may do so on more. We are also paying royalty for the use of certain inventions on which no patent was ever taken. "But," you say, "how about Mr. Heddon and his divisible brood-chamber hive?" We propose to honor and respect Mr. Heddon's rights, so far as we honestly understand them. We never made or offered for sale his hive; but should we ever do so (i. e., such a one as is specified in his patent) it would be under royalty, or such an arrangement as we could make with Mr. Heddon himself.

"But," you say, "how about the Danzenbaker patent, and his hive, as described in this issue?" That is a point which the interested parties will perhaps settle between themselves. But, again, you may ask, "Have you not been trying to evade Mr. Heddon's patent in recommending two Langstroth bodies, one on top of another, as one brood-nest?" Inasmuch as two-story Langstroth hives, through both of which the queen has had access, have been in use many years, we did not, and do not now, think they conflict with Mr. Heddon's claims. Before perforated zinc was known, queens must necessarily have had access to the several parts of the hive.

I understand that Mr. Heddon has criticised us pretty severely in the January number of his *Dowagiac Times* extra. No copy of it has as yet been received at this office, so I do not know what has been said, other than what has been reported to us second hand. In any case, we desire to arrange honorably and amicably for any invention properly belonging to another, that

we may desire to use or manufacture. Any other course would be inconsistent with the sentiment written by A. I. R. in '84, and, more than all, dishonor the Lord and Master whom we are trying to serve.

OFFICIAL CANVASS OF VOTES.

GENERAL MANAGER NEWMAN has sent the following report:

To Members of the National Bee-keepers' Union:

The canvass of all the votes received, up to the time of closing the polls, February 1, 1895, shows that 151 ballots were recorded, as follows:

FOR PRESIDENT—

Hon. R. L. Taylor, 126; Dr. C. C. Miller, 5; G. M. Doolittle, 4; Hon. Eugene Secor, 3; A. I. Root, 2; scattering and blanks, 11. Total, 151.

FOR VICE-PRESIDENT—

Dr. C. C. Miller, 114; G. M. Doolittle, 113; Prof. A. J. Cook, 102; A. I. Root, 101; G. W. Demaree, 77; Hon. Eugene Secor, 38; C. P. Dadant, 31; C. F. Muth, 22; P. H. Elwood, 16; G. W. Brodbeck, 14; G. W. York, 11; E. R. Root, 7; Hon. R. L. Taylor, 7; Mrs. Jennie Atchley, 6; Hon. James Heddon, 6; W. Z. Hutchinson, 4; S. I. Freeborn, 3; R. F. Holtermann, 3; Frank Benton, 2; C. W. Dayton, 2; H. G. Acklin, 2; scattering, 17.

FOR GEN'L. MANAGER, SECRETARY AND TREASURER.

Thomas G. Newman, 149; blank, 2. Total, 151.

Although several have expressed their desire for a change in the officers, the members have decided to keep the management in the same hands for another year.

Mr. G. W. Damaree, who has served as vice-president for 10 years, now states, both publicly and privately, that he *positively declines* to act on the "advisory board" for the coming year, as he desires a change in the "official board." This will elect Hon. Eugene Secor, who has received the next highest number of votes. We welcome friend Secor most heartily, because of his eminent ability, influence, and sound judgment. This is a place where the latter is a very necessary qualification, and the sagacity of the Board is sometimes quite severely tested.

Several more decisions from Supreme Courts are needed as precedents, for the guidance of judges in lower courts, and one of these, I hope, is about to be obtained, covering a very important point.

The "Treasury" being in a satisfactory condition, the Union is fortunately in a position to *demand justice*, and protect the rights of its members in the courts of law.

This is a place where "money counts." If the Union were a bankrupt concern, quite powerless to "help in time of need," its influence would be infinitesimal, and itself a laughing-stock for all. The "sins of war" makes all the difference in the world.

THOMAS G. NEWMAN,
General Manager.

BEGINNING with this issue we shall allow space in our Trade Notes department for inventors to describe some of their recent inventions as they come forth from the Patent Office. In doing so I shall neither indorse nor condemn, but let the inventions stand on their own merit.

HIGH-PRESSURE GARDENING IN THE SWAMP WOODS, OR HAMMOCKS, OF FLORIDA.

Another trip on the cars, and we struck Titusville. I have just been out in the woods with friend Fröscher, and have seen something that I shall not soon forget. Imagine a low piece of ground covered with palmetto-trees, with all other growth cut away. Now imagine open ditches, two or three feet wide, cut through at intervals so as to draw off the water. The bottom is pure white sand; and the water, as it runs through, is as soft as rain water, and as clear as water well can be. These ditches are cut through at intervals of from one to five hundred feet, as may be needed to take off the surplus moisture. The gardener goes to work and gets out every thing except the palmetto-trees. These are all, or nearly all, left standing. They are, on an average, perhaps ten or fifteen feet apart, may be farther. When they have oak stumps difficult to get out, rubbish is piled on them and burned. Then the ground is grubbed up into ridges and furrows, say averaging 25 or 30 inches apart. The kind of soil selected for this sort of gardening is a soft, black, sandy loam. It looks a good deal like what we call woods dirt. On the tops of these ridges the crop is planted. This morning we saw a patch of beans. The plants stood evenly three or four inches apart. They were large enough to have four or six beautiful, thrifty leaves to each plant. As we approached the garden the luxuriant bright green, partly in the shadow of the palmettoes, made one of the prettiest sights I ever beheld in the way of gardening. Closer inspection showed thrifty tomato-plants, some of them nearly a foot high, standing at intervals in the furrows between the beans. These tomato-plants were saved at the time of the freeze by being bent down and covered with the loose dark soil; and now right here is a strange phenomenon. The beans and other plants grow just as thrifty right close up to the trunk or stump of a palmetto-tree as anywhere else. The gardeners say the beans require some sort of fertilizer that the palmetto does not use; and it has been suggested that the palmetto is a sort of air-plant, so that it really takes very little from the soil. But the principal object in leaving these palmetto-trees is, that they keep off frost from the beans and tomatoes, and also keep off cold winds and the extreme heat of the sun. In fact, it makes a sort of shaded greenhouse during the heat of the middle of the day. The gardener works in a shady woods, with damp soft soil under his feet, and pure running water always close at hand. The gardens seem to be in small patches of from one-half to a whole acre. Around this little circle or square, a thicket of woods is left for protection. Of course, no horses are used. The work is all done by hand: but the soil is so light and soft that hoes and steel garden-rakes enable the workman to prepare the ground and keep out the weeds, with comparatively little labor. Besides beans and tomatoes we saw cucumbers, lettuce, radishes, cabbages, onions, and, in fact, almost every thing grown in gardens, cared for in this way.

Friend Fröscher has his gardening ground so arranged that he can shut up the ditches and raise the water to any height, just as we do in our celery-grounds north; and, in fact, he has made quite a little start in producing fine celery, to be shipped to the northern markets

during the months of March, April, and May, when celery is out of the markets in the North. The bleaching is all done with boards. The principal impediment just now is the matter of express charges. For an illustration: Five boxes of celery shipped to Philadelphia brought \$12.00. The express companies took \$9.00 of the \$12.00, leaving friend Fröscher the remaining \$3.00. May be this matter can be remedied when the express companies have more competition, and the work is more fully established. In any place except Florida, so much shade would be more of an objection; but even up north, during our hottest summer months, I have observed that certain garden-plants do better when somewhat shaded, more especially celery.

Now in regard to rotation of crops. The friend we visited, Jas. Cole, has raised two crops of Refugee beans, picked for snap beans, of course, in a season; and he would have had three crops had it not been for the big freeze. He succeeded in harvesting and selling one crop in the fall, cleared off the ground, and planted another; got them just about as far along as those we saw to-day, when the freeze demolished them. Therefore, during ordinary seasons there would be no difficulty in getting three crops. During the very hot weather of the summer, however, they have difficulty in keeping the ground occupied, unless it is with cucumbers, pumpkins, or squashes, or some crop that bears extreme heat. Even sweet potatoes fail to do any thing if started before August or September. Friend Fröscher says they do just as well as if planted earlier.

ONE OF THE FLORIDA INDIAN-RIVER HOTELS.

For the first time we find it convenient to stop at a hotel instead of accepting invitations from bee-keepers. We were told several times that we must not fail to visit Rockledge. Now, we did not feel called upon to pay \$5.00 a day; but we chose the moderate price of \$2.50, and are abundantly pleased with the Rockledge hotels at that price. There are five hotels in the place; a beautiful, commodious drygoods store, drugstore, postoffice, etc. At the entrance to the road leading to the Indian River Hotel we found an archway of incandescent electric lights. A little railway for running baggage extends from the depot platform to the hotel. A similar one extends from the steamboat landing to the hotel. There seems to be a disposition down this way to avoid the necessity of horses. Boats on the water, that is almost everywhere; railways and plank sidewalks for Daisy wheelbarrows (and other kinds), seem to be the general plan; and, in fact, without shell roads or some other kind it takes a horse a good while, and even then considerable muscle, to get any kind of a load through the soft and yielding sand. The grounds in front of the hotels are finely lighted by electric lights and gas. Fountains are playing on the green lawns, and people are walking about in the thinnest summer clothing. Women folks are bareheaded at that. Scarcely a breath of air is stirring, and the thermometer is well up toward 80°; and yet, even in the evening we have not seen a gnat or mosquito. The porter says they "don't have any here." Steamers and craft of all sizes are on the Indian River in front of the hotels, with their lights marking out their location. We have not paid out very much money so far on our trip; but I feel just now as if I would almost give \$25.00 to have the Root family here for just an hour. Of course, I should want the grandchildren counted in. Some of the friends may think \$2.50 a day for a single individual is pretty expensive. Well, so it would be perhaps if followed up. But let me give you some of the advantages: The postoffice

is just across the way; stores and places of business, I have mentioned; boats are coming and going constantly at the wharf, right at the door of the hotel; we have beautiful, spacious, airy rooms. The parlor and even the office is carpeted and furnished in excellent style. Everything is clean, beautiful, and new. The most courteous and civil people are always ready to help and advise. I was obliged to change the tire of my wheel in consequence of running over a catfish on the beach. At least half a dozen different persons offered to help me, or bring me any thing I wanted. Last, but not least, a beautiful, cushioned naphtha-launch is in use every day, solely for the benefit of the guests of the hotel, and entirely without charge. I wanted to go over to Georgiana, six or eight miles distant, and they carried me over and waited an hour for me to make my visit.

My good friend O. N. Page, at this place, and his family, were delighted to see me, but scolded pretty severely because I came all the way down to Florida and then stayed only an hour. One of friend Page's grandchildren, a curly-headed, bashful little chap who has commenced going to school, couldn't learn to recite the vowels—a, e, i, o, u, y, because, whenever he got started, he would always run off into A. I. Root. You see, A. I. Root is such a household word at Georgiana. Here we first saw a pineapple-garden, and cocoanut palms large enough to bear; and when we saw some strawberries large enough to be red, friend Page climbed over the fence and picked a berry. Then we told the owner afterward. It seems too bad to hurry by friends who are so glad to see you in this way; but how else shall I ever get around?

Friday, Feb. 1, we found ourselves at Palm Beach. I enjoyed a ride on my wheel for several miles before breakfast. It is daylight here at half-past five, and the earliest breakfast is at half-past seven. I ran down the west coast of Palm Beach through beautiful grounds interspersed with cocoanut palms and various other tropical products. Patches of tomatoes more than a foot high greeted me at every turn. At one point I saw a beautiful garden of cacti. Of course, the frost has marred the beauty of all the grounds more or less, but not nearly so much here as farther north. Orange-trees here have all their foliage, and the fruit is said to be uninjured; but very few oranges are grown in the vicinity of Palm Beach, it seems. The grounds around the great hotel, The Royal Poinciana, are not only beautiful, but are kept constantly neat and tidy. The hotel at Palm Beach I should call the handsomest structure of its kind I have ever seen anywhere. The Ponce de Leon, at St. Augustine, is admired by many, and is called the finest in the world. But what prejudiced me at first glance was to see the breaks in the paint, and unsightly stains running down on what I supposed to be stone work. All over the edifice were glimpses indicating that the building was cement and veneer, and not what it purported to be. The Moorish architecture, I admit, is beautiful. The hotel here is built to represent wood, and nothing else. The wood is neatly painted. There are no rusty spots or unsightly cracks caused by the wear and tear of the sun and storms. It is perfectly bright, clean, and handsome. I tried my wheel on the ocean-beach; but the sand seems to be too soft down here. The walks along the shores of Lake Worth at Palm Beach are very fine for wheeling. Along here, as at Rockledge, the shores are mostly lined with a queer rocky formation called coquina. This seems to be all made up of fragments of shells. In many places it is made up entirely of polished fragments, or of shells almost pure white, these fragments being ce-

mented together by what seems to be a transparent cement. It has been suggested it was first made solid by the salt of the ocean, and, after the lapse of time, by some change caused by the sun and air, this salt formed an insoluble compound. The stonework of the Ponce de Leon is mainly of this material. It would seem as if there were fragments of shells enough in Florida to furnish lime for the world. A word in regard to the multiplication of shellfish.

Friend Hart showed us something that looked like kernels of sweetcorn strung on a thread. He said that these eggs were produced by the fish that inhabits the great conch-shells. Each grain of corn, as it appears to be, in due time bursts open, and is then found to be full of little shells not larger than a cabbage seed. These shells grow. I don't know how rapidly, until they make the great heavy handsome shells we find and use so often as ornaments. The animal, when it is alive in salt water, has a neatly shutting lid that it can pull down and be almost absolutely beyond the reach of its enemies. The old mound-builders used these shell-fish for food, for we find the remains of many conch-shells in the oyster-shell mounds, with a hole broken in a particular point to enable them to extract the fish for food.

SHALL I RECOMMEND FLORIDA AS A PLACE FOR A POOR MAN TO GET A LIVING?

In some respects, no. Florida seems to be a camping-ground for rich people—millionaires if you choose. Almost every man who has made a fortune in soap, chewing-gum, or any such commodity, has a winter residence in Florida. There are almost no manufactures or other similar industries, except factories especially for these rich people. For instance, there are ice-factories in every considerable town. Then fishing is constantly going on to supply the great hotels and fine residences. Orange-growing seems to be the one great industry—that is, for a crop to ship long distances. There is no doubt a good opening, and always will be, for gardeners who will furnish extra fine products for the great hotels. Every one who raises a crop, however, must look out that he has a market for all he raises; and he must see to it that he can get a product into the market before it goes to waste on his hands. I should say there is plenty of opportunity to get good wages in most places where one has the energy and strength to work during the hot weather. I warn you, however, that it is the grandest place on the face of the earth to sit on a cool piazza and rest instead of working out in the sun; and if you don't look out you will find yourself giving way to this prevailing fashion. A great deal of the work done is to accommodate tourists and pleasure-seekers. The yachts and launches that are flitting about on Lake Worth right before our eyes, while we take down these notes, are far more for pleasure-parties than they are for business.

This morning at six o'clock the weather was oppressively hot; but by eight o'clock we had a brisk breeze on the water that has several times made me think of putting on my coat. Here for the first time we find cocoanut palms scattered about almost everywhere. Young trees are starting up all through the brush, especially along the bank of the lake. In the little flower-beds in the neat cottage where we are staying are cocoanuts lying on top of the ground, with sprouts from a few inches to a foot or more in length. The smaller ones have as yet no root at all, but those with the larger tops have roots starting out from the other end of the nut, reaching down into the ground. It would seem that they are the easiest things to grow in the world. We are much indebted to

Mr. Wallace R. Moses and Dr. Stites, of this place, for points of information, and many courtesies. When I asked if cocoanuts grew naturally at Palm Beach, Mr. Moses said they did not; that, if he was correctly informed, they originated from a wrecked schooner containing something like 40,000 nuts. These nuts were washed up on the shore, and took root in the way I have described, thus lining the shores with these beautiful tropical trees with their handsome fernlike foliage. These fern-leaves, however, are anywhere from ten to twenty feet long. The nuts hang in great clusters just below where the branches start out at the top of the tree—each nut, of course, being enveloped in its husk. So far as I can gather, however, cocoanut-growing is not as yet a paying industry here. The sharp competition from Cuba seems to stand in the way. The people here gather enough of the nuts for their own use, or for retailing in the Florida towns, and that is about all. In the evening Mr. Moses brought his wife and children to the cottage where we were stopping, and we had a very pleasant visit. Mrs. Moses is quite an enthusiast with poultry and ducks. You know I have suggested that this business could be profitably carried on in Florida. Here are some figures she gave us. During the month of January, just finished, they sold 691 eggs from 58 laying hens, and 607 eggs from 32 ducks. The hens' eggs brought 40 cts. a dozen, and the ducks' eggs 35. This large price was probably owing to the demand for eggs from the large hotels and boarding-houses. Mrs. Moses said if I gave these figures in print I must be sure to state that nearly all of the food for the poultry had to be purchased from the North. They also have to shut up the poultry nights and let them out again mornings, as the opossums and other enemies would be sure to make short work of them.

West Palm Beach has all grown up in one year—at least I am told there were only two houses there a year ago. There are now toward one hundred houses in the place. All kinds of business are carried on. Two papers are published. Beautiful drinking-water is pumped from a fresh-water lake half a mile from the center of the town. The bottom of the lake is of the most beautiful pure white sand. It is about as nice as water can be for any purpose. The pumping-station furnishes an abundant supply for the great hotel, for the town, and for the railroad. Building is going on briskly on almost every street. You can see the carpenter and the owner of the property working together like a couple of brothers, and almost the next day a grocery, barber-shop, restaurant, or printing-office will have out a newly painted sign. Of course, a good many things are pretty crude and unfinished; but the weather is so warm, something that looks like a house is all that is needed. As there is never any mud, it is not a difficult thing to keep the floors and verandas clean. Almost every house has a porch in front, and plenty of rocking-chairs. The latter are generally in use, for almost every one prefers to stay out of doors.

On Saturday, Feb. 2, we found ourselves at the home of O. O. Poppleton, who is so well known to most of the readers of GLEANINGS that a further introduction will hardly be necessary. Here we seem to be right in the midst of the pineapple industry, and this is so strange and unusual that I hardly feel able to describe it accurately, much less teach the people here how to manage their gardening or farming. In the first place, I rather expected friend Poppleton to meet us at the train with some sort of horse and carriage; but he came with a boat. Pineapples are a sort of air-plant that grow in

the clean white sand. When I asked him if stable manure wasn't cheaper than the chemical fertilizers they were using, the question arose, where would they find any stable manure? for, although there is quite a community of people gathered here, there is not one of them who has a horse or cow or pig.

Just at this point we were interrupted by the visit of a boat containing a couple of Indians—one of them a boy of seven, the other a young man of twenty; at least, the latter said he guessed he was about twenty. Although the day is so cold that I have been wearing my fur cap and overcoat on account of the chilly north wind, these Indians were bareheaded and barelegged—in fact, bare almost all over, especially when the wind blew aside their clothing, which was exceedingly short. The little fellow could not talk our language, but he could smile in a way that was quite taking. They were of the Seminole tribe, the remnant of the native Indians of Florida. They stepped out into the water, without the least hesitation, and stood there while we talked. I asked the older one a great many questions. Some of them evidently taxed his learning and intelligence somewhat, for at first he would say he didn't know; and then after studying a while he would give an answer a little at a time. He said he was married; had a squaw of his own; that his name was Billy Ham. He said they had over in their camp a "horse-wagon." I joked friend Poppleton on being behind the Indians in methods of locomotion. The boy had nothing on but a thin calico shirt, and his hair was clipped except a tuft just on top, and yet he seemed to be perfectly indifferent to the brisk north wind. I told friend P. I would give thousands of dollars for such a constitution as these Indians have. They were exceedingly pleasant and friendly, and I could not but admire the manly frankness of the older one, especially his readiness to say he didn't know, when such was the case, and his willingness to give me all the information he could possibly scrape up on any point I was curious about. Although help is needed on the pineapple grounds, and good wages are offered (\$1.50 per day for good stout men), these Indians never hire out, friend P. says. The squaws do the work while the men shoot deer, and then peddle them out among the white people, with their canoes. After he had sold us a half of venison he inquired for oranges and then honey. We sold him some of the latter for 60 cts. a gallon, he promising to bring back the pail. Friend P. says they are straight and fair; have one price for what they have to sell, and always pay down without any attempt to beat down the price they are charged. Billy had a tunic of many colors, with flounces and fancy stitching that was so neatly done a schoolgirl might be proud of it. When I asked him who made it he answered, "Me," pointing to himself; and when I expressed wonder and surprise he said they had a sewing-machine. You see, the Indians are beginning to "catch on" to the latest form of civilization. The men are doing the women's work, and the women are doing—well, we don't know what they are going to do when they get settled down to it. Now, the Bible says it is wicked to covet; but I want that seven-year-old boy more than I have wanted any thing else in a long time. I feel just as sure I could bring that boy up, God helping me, so he would be a good boy and a Christian, as that I could grow pineapples if I lived next to friend Poppleton. Well, suppose we get back to the pineapples, as we are pretty nearly around to it.

When I asked friend Poppleton if stable manure wouldn't be cheaper than chemical fertilizers, he laughed at me and asked where they

would go to get stable manure. In the first place, there are no stables; second, there are not any horses anywhere within miles, and there are no roads on which to travel, even if there were horses. Neither are there any wagons. Every house is planted by the river, and in front of the door there is a wharf or landing where one or more boats are tied up. People go everywhere in boats. They ship their products in boats. The oranges and pineapples are all wheeled down to the landing in wheelbarrows; and, by the way, the manufacturers of wheelbarrows will please take notice right here. They are to make some with a light steel tire at least four inches wide. Furthermore, this steel tire, and, in fact, the whole wheel, is to be galvanized so it will stand the salt sea-water. There are miles and miles of country down here where wheelbarrows are almost the only vehicles used in gathering crops, and they should be made so they can run over the soft sand, and go clear down to the beach and into the salt water.

A LETTER TO MY SUNDAY-SCHOOL CLASS; WHAT I FOUND IN THE SALT WATER.

It was the last day of February that I stepped on board a little steamer to ride from Punta Gorda to Fort Myers. Our route lay down through Charlotte Harbor, around Pine Island, and finally up the Caloosahatchee River. While most of the passengers proceeded to pass the day reading papers, talking politics, etc., I decided to find out what I could of the inhabitants of the tropical deep. I felt sure that, by practice and study, I could learn to see fish in the water, like the old veteran fisherman, and in a little time I was rewarded by seeing great numbers of a round light-colored fish which the captain said were "needle-fish," a species of gar. These dart about with incredible rapidity, and one must get his eye trained before he can follow them. They have a long ducklike bill, and the fish are from one to two feet in length. As the boat comes along, they, in their fright, often run right in front of it, and sometimes even jump out of water. Very soon I thought I could in many places see the bottom, and the captain told me I was right.* The sea-water is often very clear and clean, having only a greenish tinge; and the pure white sand at the bottom makes it very easy to see any object. Think of looking over the side of a steamboat, and seeing the bottom as you go along, and seeing also almost every object quite plainly. I soon found crabs and turtles; and finally I started back in fright, for a hideous creature as big as a cooking-stove, with spotted wings, came almost up to the surface, and seemed to care very little for me or the steamboat. His tail stuck out like that of a turtle, and his wings were painted as gay as if made of curtain calico. The captain said it was called "whippera," and is near akin to the order of devil-fish.

A school of porpoises came next, and they evidently proposed to give me a better chance to get acquainted. They rolled and tumbled partly out of the water until I became very anxious to see the whole of one at once; and just about then one of them seemed to say, "All right; we will do almost any thing to accommodate 'brother Root,' since he has come clear down here to see us." And, suiting the action to the word, he hopped clear out of the water, going out head first, and going back in head first. Now, boys, think of a fish as big

as any one of you doing that, and you get something of the idea. About this time I said to the engineer I would give a silver dollar to see one of these chaps up close; and almost as soon as I had spoken, two of them turned summersaults so close to me I could easily have touched them with a common fish-pole. Well, now, even this was not all of the "show," for I had hardly taken my position again at the prow of the boat, down near the water, when I saw two beautiful cream-colored fish, just before the boat, scudding along like a nicely matched pair of colts; they were almost as large as horses, and one could easily imagine they were pulling the boat exactly as horses pull a buggy. I thought they were running in front of us, as cows get frightened and run before a locomotive; but the mate of the boat said they were only big porpoises "at play," and he says they often run in front of the boat and play in just that way. Pretty soon the captain asked me to leave my fish and come to dinner; and then the cook of the boat said he had prepared some "speckled trout" expressly for "Mr. Root's dinner;" so you see I had a nice time all around. For dessert the cook brought us some very fine guavas. If you don't know what a guava is, just imagine a nice strawberry as big as a large peach, and you will have it pretty nearly. They grow on trees, and the trees bear fruit almost every month in the year.

I spent the whole day in the way I have told you, and enjoyed every hour of the trip. One secret of the enjoyment was, that I made friends with every one of the five men who run the boat. Some of the passengers came to see the wonderful things I was finding down in the "briny deep," but they said they couldn't see a thing. You see, they hadn't the patience to sit down to learn how. If we only look carefully we shall find—

Sermons in stones, books in running brooks,
And God in every thing.

Everybody is catching fish down here. The mate told me a party of "women" who stood on the dock and threw in their lines caught *two hundred* "big ones" in about two hours.

A. I. R.'S NOTES OF TRAVEL: DOES HE PAINT THE PICTURES IN TOO ROSY COLORS?

Mr. Ernest Root:—Excuse my freedom in offering a few words in regard to the last travels through Alabama, Georgia, and Florida. I am surprised to see that country so enthusiastically—yes, "eccentrically" palmed off. It is "just slick," that "Dixie Land," etc.; and this, too, notwithstanding the disastrous drouth, hard freezing, poor and sandy soil, poor houses, no windows, etc. It is ridiculous. I have seen houses in the South made of *barrel-staves*, and many other things according. I am sorry that your father started out in such high "tune," "big-bug like." He has forgotten all about the thousands in Florida who lost nearly all they had by the last disastrous frost, when he speaks of Jacksonville. That's all right for rich men; but how is it for those whose means are limited, who are encouraged by such writings? I could send you letters from Florida, from men who live there, that would open your father's eyes. One of my neighbors sold his nice home here, on account of just such reports, and went to Florida last fall, and is now back again, after spending nearly all he had. I have also seen the same thing through Texas this winter, and that is why I write this, not to find fault with your father, for he has written many good articles, from which I have learned much.

I was at the midwinter convention at Mrs. Atchley's, at the time of the hard freeze. The

*It may be well to mention that our little steamer is made for shallow water, and draws only about six feet; therefore, when the water is from seven to ten feet deep, and *clear*, I can see almost every fish, little and big.

"Sunny Southlanders" didn't have much to say, but all closed up to the fireplace.

I remember you and your mother well, from seeing you at the World's Fair convention. It struck me you were "mother herself" in looks, outside and inside. C. THEILMAN.

Theilmanton, Minn., Feb. 8.

[This, as our readers will see, was forwarded to A. I. R. himself, who replies.—E. R.]

Many thanks, good friend T., for your timely caution; but I must think you overestimate the danger. If you read my notes carefully you will see I mentioned the poor dwellings with wind blowing under the floors, etc. Surely no one will think of "pulling up stakes" and rushing down to "Dixie" on account of the pen-picture I gave Huber. It was mostly to contrast the difference between Dixie, and snow a foot deep and zero, that I wrote it. Suppose I should, in my travels anywhere (say through *Minnesota*, for instance) write up all the disagreeable things, tell of the tumble-down buildings, deserted farms, untimely frosts and drouths, etc. Would anybody want to read such "travels"? and would it do any good? Even our pleasant town of Medina, where I have lived, grown, and prospered, is often called the "meanest place on earth;" "farming doesn't pay," and all kinds of business are "overdone," to people who always wear that kind of "spectacles." Now, Florida is much like Medina, unless you look for its bright side, and take in its *redeeming* features. There are lots of tumble-down houses, slipshod gardening, and dilapidated orange-groves. By the way, a neglected orange-grove is about as *sorry* a looking place as one can well imagine. Perhaps there never was a time more unfavorable for writing up Florida than this very winter I have chosen; but you see by my notes I still find a world full of interesting things—a world full, too, of opportunities to go to work and get *good pay* for your work. Back of it all, I see continually the hand of the *unseen God*, the hand of the *living Father*.

Thursday Feb. 7.—During the afternoon at Gifford, Florida, the thermometer stood at 72°. Next morning at sunrise it was down to 22°—a fall of *fifty degrees* in 12 hours! The greater part of all the garden stuff in the State was killed outright, the *second time*, in just one winter. People had just begun to recover, and to get courage, since their December losses, and now here we are again. I say *we* for I feel as if I were a part of Florida now. Shall I write this up as a part of the bad features of Florida? Of course, it indicates that *now* and *then** we must expect disasters down here. But, dear friends, crops fail and losses occur *everywhere*.

Since I have been a Christian my disposition is to see sunshine, even through black clouds; and my travels in any land will take in naturally the sunny features; but I think that, if you look carefully, you will find I have faithfully mentioned, also, most of the unpleasant things.—A. I. R.

HOME AGAIN.

Here I am, March 13th, back again in the land of mud, dampness, and frost. Florida is gone—gone in a brief 48 hours; gone with its clean sand and sunshine; gone like a bright dream. I have traveled through it something like 1500 miles, and didn't find mud enough to scarcely need to brush off my pant-legs once. Mrs. Root will tell you it *must* be a wonderfully *clean* place. True; but you can't get any

crops down there like those here on our Medina clay, without a tremendous sight of fertilizers of some kind, and you have to keep putting on the fertilizers for every crop you raise.

After leaving the East Coast I visited in succession Sanford, Oakland, Tarpon Springs, St. Petersburg, Manatee, Tampa, Thonotosassa, Lakeland, Bowling Green, Avon Park, Kissington Springs, Homeland, Bartow, Punta Gorda, Fort Myers, Orlando, Tavares, Mt. Dora, Blue Springs, Orange City, Lake Helen, Palatka, Lake City, and Green Cove Springs. The only place where I found orange-trees full of foliage, fruit, and blossoms, was at Ft. Myers; and I made in that vicinity a still bigger "find" for bee-keepers—at least, I consider it so. You have all doubtless noticed what our good veteran friend Poppleton has to say about the destruction of the black mangrove on the East Coast. Well, imagine my feelings when the men who ran the steamer told me the rank vegetation which covers the numberless islands on Charlotte Harbor was *black mangrove*, and almost nothing else. As nearly as I can learn, but few bee-keepers have ever located on or near these islands; but I am told the woods is so full of wild honey it is brought in in large quantities. We shall at once open up correspondence with all the bee-keepers we can find in that vicinity. Here seems to be a chance for the migratory brethren. This point is so far south, the mangrove seems to be entirely unharmed. My Florida notes will, in full, go through several months yet. I shall be glad to answer any questions that my notes do not answer.

KIND WORDS FROM OUR CUSTOMERS.

The much-talked of Crane smoker is received, and was thoroughly tested, which resulted in proving all that is claimed for this pride of the apiary. Reibersville, O., Feb. 25. J. A. GOLDEN.

Order No. 35,286, you shipped Feb. 8. I received Feb. 28, 5 boxes. They are in good shape. The foundation is very nice, good color—a great deal better quality than I have been using. The freight was very low—78 cents. I shall put the hives together next week, then I will write you how I like them. WM. R. PAGE.

Avon, N. Y., March 1.

BEST LOT OF BEE-FIXTURES HE EVER HAD.

Goods came to hand all right. Some of the boxes were split pretty badly, and the lamp was broken; but I must say they were the best lot of bee-fixtures I ever had. Everything fit nicely. I am 67 years old, and have had bees since I was a boy. Cline, Tex., Feb. 2. W. H. BEASLEY.

We have sent A. I. Root one of the latest improved queen-traps. Those who purchase traps of him the coming season will get the most complete queen-trap ever used. The new trap will soon be illustrated and described in *GLEANINGS*.

A. I. Root has sold more of our drone-and-queen traps than any other firm. We predict that, in the near future, the Root's will be about all the bee-supply dealers in the country. Medina will be the head center, and their supplies will be found on sale in every State in the Union. They now have a branch supply office in the State of Florida.

"Quality, not cheapness," is their new motto. That has the right ring to it. Success for Bro. Root was established years ago.—*American Apiculturist*.

THAT CAR OF BEE-GOODS, AND HOW THEY PLEASE.

The car of bee-keepers' supplies has arrived, and is unloaded. I have not had a chance to check up all the small articles; but so far as I have checked, everything is O. K. The hives and sections are even nicer, if any thing, than the last car was, and we are all delighted with the "bee notions," as we call them. I think you can count on an order for the next car of goods I need. W. O. VICTOR.

Wharton, Tex., Mar. 8.

*I believe the Weather Bureau will bear me out in the assertion that no such winter has occurred here before in *fifty years*.—A. I. R.

I will offer for sale in April, tested Italian queens bred for business and gentleness. Leather-colored queens at 90 cts. each; 3 for \$2.50; 6 for \$4.50. Tested golden Italians, yellow to the tip, bred for business and beauty, easy to handle, \$1.00 each; 6 for \$5.00. Will have untested Italian queens ready to mail the 1st of May at 75 cts. each; 3 for \$2.00; 6 for \$4.00. Bred from the best 5-banded stock, free from disease.
W. A. COMPTON, Lynnville, Giles Co., Tenn.

WINTER soon is over!

And if you contemplate buying Bees and Queens You will do well to write For prices to

eltr

LEININGER BROS., FT. JENNINGS, O.

W. O. Victor, of Wharton, Tex., took

45,000 Lbs. of Honey in 1894.

He offers Italian Queens—good, old-style honey-queens—untested, first order, to any address, at 50c each. Also bees in any quantity; 450 colonies to draw from. **Root's goods constantly in stock.** Prices to suit the times. Buy near home, and save freight.

25 Imported Carniolans

Ready for immediate delivery at \$5 each. Bred in 1894 at the most elevated point among the Carnic Alps where bees are kept. Daughters of these queens ready in April, \$1 each; \$10 per doz. Address

The Carniolan Apiaries, Charlton Heights, Md.

2 and 3 frame nuclei cheap by the dozen.
AUG. LEYVRAZ, Francis, Fla.

The Southern Home of the Honey-Bee

Is ready for your orders for 3 or 5 banded queens, as good as the best, guaranteed free from paralysis. Warranted queens, 75c each; tested, \$1.00. After June 1, warranted, 50c each; tested, 75c each. Good breeders, \$2.00. Straight 5-banded, or "faultless," queens, \$2.50 each. Special prices on lots, also to the queen-dealer. Safe delivery and satisfaction guaranteed. Circular free. Address

HUFSTEDLER BROS., Clarksville, Tex.

MUTH'S HONEY-EXTRACTOR, SQUARE GLASS HONEY-JARS.

Bee-keepers' Supplies in general, etc., etc. Send for our new catalog. "**Practical Hints**" will be mailed for 10c in stamps. Apply to

CHAS. F. MUTH & SON, Cincinnati, O.

Hives, Sections, Foundation, Bees, Queens,

Or any thing a Bee-keeper Needs.

In April and May I will receive from the South, (via steamer) cases of 8 frames of capped brood, well covered with bees. These are *just right* to build up colonies with.

Single frame, 90c; 4 frames, \$3.25; 8 frames, \$3.25; 8 frames, \$6.00; 16 frames, \$11.00.

Untested queens included for 90 cents.

Everything sent from this city. Let me know your wants. Catalog free.

I. J. Stringham, 105 Park Place, N. Y. City.

Golden Queens From Texas.

My queens are bred for business, as well as for beauty and gentleness. Safe arrival and reasonable satisfaction guaranteed. Untested, \$1.00; tested, \$1.50.

Write for price list.

5-16ei

J. D. GIVENS, Lisbon, Texas. Box 3.

1895 To my customers and friends: Please remember that W. H. Laws is again headquarters for Italian queens. I breed nothing but large, well-developed queens, either Golden or Leather-colored. My Golden strain is from Doolittle's original one-hundred-dollar queen, sent me after he had reared over 1000 queens from her. For business and beauty, my bees are unexcelled. Price of queens, each, \$1.00; 6 for \$4.50. Tested, \$1.25. Breeders, \$2 to \$3. Address

W. H. LAWS, Lavaca, Seb. Co., Ark.

Dovetailed Hives.

Sections, Extractors, Smokers, and everything a Bee-keepers wants. **Honest Goods at Close Honest Prices.** 60-page catalog free.

Early Queens By Return Mail.

Choice Tested Italians, vigorous and prolific, \$1.00 each.

These queens were reared in the fall of '94 for our early spring trade, and are guaranteed to give satisfaction.

J. W. K. SHAW & CO.,
Loreauville, Iberia Parish, La.
Please mention this paper.

HONEY MARKET.

The demand for extracted honey is good, and we could handle some more choice lots of basswood honey in 60-lb. cans. If you have any to offer, let us hear from you with sample. Our prices for comb and extracted honey remain as quoted in our last issue.

ALSIKE CLOVER SEED.

We have a good stock of choice seed, and there is no better time to sow than the present month. Market is usually firmer, and prices higher, at this season and later. This year seems to be an exception so far. It is being sold at about the same price as medium and large clover. Our price for the present is, \$2.00 per peck; \$3.80 per half bushel; \$7.20 per bushel; \$14.00 for 2 bushels; 5 bushels or over, at \$6.60, bags included in each case.

BUSINESS AT THIS DATE.

Orders are coming in freely, and we have several railroad orders booked not yet shipped. We have been obliged to shut down our wood working department for a week to make repairs in our boiler and steam-plant, which could not wait any longer. Besides, la grippe has come upon us with force, and temporarily laid off for a few days some of our most efficient helpers. If there is some little delay in attending to your wants, we trust you will bear with us. Providence permitting, we trust all will be at their post again soon with their usual vigor.

BEESWAX WANTED.

The scarcity of beeswax continues, and markets are bare, and prices are stiffening. If this continues much longer we shall be compelled to make another advance in the price of comb foundation. We are hoping that, with the opening of spring and the return of the junk peddler to his usual summer vocation, the supply may be more plentiful, and the upward tendency of price checked. We increase our offer again 1c per lb., and will pay 29c cash, 32 in trade, for average wax delivered here. We need all we can get for making comb foundation, and for the present we will not offer wax for sale.

MAPLE SUGAR AND SYRUP.

As we go to press, no new maple sugar or syrup has been brought to market; but we are daily expecting it, and propose to furnish it as in former years. We usually have three grades of sugar which we will offer for the present at the same prices as formerly—8, 9, and 10 cts. per lb.; $\frac{1}{2}$ c less in 50-lb lots; 1c less in barrel lots. If price should be lower, we will give you more sugar for the money you send. Maple syrup of choice quality will be worth \$1.00 per gallon in 10-gallon lots; single gallon, \$1.10. We shall be pleased to book orders for the first supply that is brought in; and if prices are lower we will give you the benefit, and quote in next issue the best prices we can make.

A BOOKLET ON BEES AND FRUIT.

This is about the season of the year, or will be soon, when the interest of the bee-keeper and fruit-grower sometimes comes in conflict. It will be remembered that, last year, we got out a special pamphlet showing that bees and fruit do not conflict; that they are mutually interdependent on each other to a very great extent. This year we have a revised booklet of 16 pages that gives all the evidence that we have been able to gather together for the last three or four years, boiled down in a nutshell; and the matter is put in such a way that the fruit-grower, if he is intelligent and fair, will be willing to accept the evidence, and thus unpleasant feelings and perhaps a suit for alleged damages may be averted. We will furnish it at the bare cost of printing, postage, and wrapping, because we feel that they ought to be very liberally distributed in almost every locality. Price for 25, 25 cts.; 50 for 40 cts.; 100 for 75 cts., postage prepaid in each case.

THE SEED BUSINESS MARCH 15, 1895.

I find our people have been doing quite a brisk trade during my absence, and certain lines of seed have advanced considerably, owing to the widespread drouth of last season. I shall, however, continue to furnish every thing at the prices given in our catalog, with the exception of the Red Wethersfield onions. Instead of the prices given in the catalog, read as follows: Oz., 10c; lb., \$1.25; 10 lbs., \$10.00. We can fill orders for all kinds of potatoes, at the prices given in our issue for Jan. 15, with the exception of the second-size Rural New-Yorker. These all run so large that there is no more second-size left.

I would call special attention to our late-grown Monroe Seedlings, such as we had last year. They were dug and put into the cellar at the very last minute. In fact, our grower, Mr. Wilbur Fenn, of Tallmadge, O., came pretty near getting caught by the frost; but he managed to get his whole crop into the cellar in nice shape. The consequence is, they are as nice and firm as the day they were dug; and if you want some first-class table potatoes, I think these will suit; and at the price we offer them, \$2.50 per barrel, they are almost as cheap as any thing you are likely to get in the market, for table use.

Now in regard to shipping potatoes. As soon after the 1st of April as the weather seems favorable, we send out all potatoes, unless we are notified to the contrary by the purchaser. If not notified, we shall expect them to go at your risk. Therefore please write us at once, if you want us to keep your potatoes for you later than the 1st of April. We have arrangements to keep them clear through the month of April, with very little danger from sprouting. A. I. R.

VEGETABLE PLANTS READY MARCH 15.

Our boys, Fred and Frank (the ones who put the roof on the greenhouse), have managed so well in my absence that we now have a fine stock of cold-frame cabbage-plants, onion-plants, lettuce-plants, and celery plants, ready to send out. We have also a splendid lot of both one and two year old asparagus-roots; also rhubarb-roots one year old, and large ones for forcing in hot-beds, or under the benches in greenhouses. For prices of all the above, see our catalog, mailed free on application. Large rhubarb-roots, just right for forcing, for early pie-material, \$3.50 per 100 roots. These latter (the large roots) are packed in barrels, and shipped by freight from Mercersburg, Pa. A. I. R.

At present writing, March 14, the season is quite backward; in fact, no maple sugar or syrup has been brought in. This is exceedingly unusual, as we generally get more or less during the month of February. A. I. R.

Kind Words From Our Customers.

I have a fault to find with GLEANINGS—it takes so much time to read it! I hardly get one half read until the next one comes. It is all cream and no skim milk, as they say. DANIEL E. ROBBINS.
Payson, Ill., Mar. 6.

OUR GOODS NO. 1 IN WORKMANSHIP, AND CHEAPER THAN THE RAW MATERIAL.

I received the hives, etc., to-day, in good order, and am more than satisfied with them. Every thing is finished up in a No. 1 workmanlike style; and after paying freight I find they come cheaper than the raw material. I am sorry I did not order more; but as I am an amateur I will make out with what I have this year. FRANK WOOLLARD.
Savannah, Ga., Mar. 9.

B. WALKER, Evert, Mich.

We would not have expended

HUNDREDS OF THOUSANDS OF DOLLARS

doing galvanizing, for which we made no extra charge, had there not been merit in it. Galvanizing consists in coating the strong but most perishable (in thin sheets) metal, steel, with the almost indestructible (even when very thin) metals, zinc and aluminum. If there were not great merit in galvanizing, no one would pay 1/4 more for galvanized barrel wire or sheet iron than ungalvanized costs. If we were making painted windmills to-day, we should furnish an

8 Ft. for \$15

That is a good price for an 8-foot painted windmill.

WE BUILD FOR THE AGES. WE WOULD NOT SELL YOU A POOR, PAINTED WHEEL, FOR AN YVANE OF METAL GALVANIZED BEFORE BEING PUT TOGETHER, IF YOU WOULD PAY US DOUBLE PRICE FOR IT. We build the best we know, and knowing that painted thin sheets are practically worthless, we have nothing to do with them. The enormous cost of preparing to do galvanizing, and of doing it well on a large scale, deters others. SOME BUY GALVANIZED SHEETS AND PUNCH AND SHEAR AND MAKE THEM UP AFTERWARD. WHEELS OR VANES MADE OF GALVANIZED SHEETS RUST OUT FIRST AROUND THE RIVETS, JOINTS, AND EDGES, AND ARE, THEREFORE, NOT SO GOOD AS PAINTED ONES. How any concern can get our prices for painted windmills and painted towers, or those made up of galvanized material, cut, sheared and punched after the galvanizing is done, can only be explained by the fact that people who buy them are ignorant of the value of galvanizing. We now galvanize everything after it is completed, even bolts and nuts. We galvanize with the most improved processes and in the most perfect known and attainable manner.

The process: When a section of an Aermotor Wheel is all riveted up, completed and cleaned of rust and impurities, it is immersed in melted zinc there until it becomes until every crack, and opening of every closed up and saturated molten metal, and pieces composing the soldered and welded then you have some- during and reliable. It is doors cannot afford to do it. aluminum melted from one silvery white coating which every portion of the Aermotor zinc and aluminum when a time, forms, with the steel, alloy, which cannot be indestructible. In our prices of wind- mills, illustration of what we REDENIGING AN OLD IT IN INFINITELY SUPERIORLY SMALL- THE OFFER OF AN ALL-STEEL VERY SUPERIOR FEED CUTTER, WORTH \$10 AS PRICES GO, AT \$10, IN OUR NEXT AD. WE SHALL OFFER YOU SOMETHING OF STILL GREATER INTEREST. Aermotor Co., Chicago.

 W. ATLEE BURPEE & CO., Seed Growers, PHILADELPHIA.

HONEY COLUMN

CITY MARKETS.

DENVER.—Honey.—There seems to be an improvement in our market; still, the prices remain about the same. No. 1 comb, in 1-lb. sections, 11@12; No. 2, 9@10. Extracted, No. 1 white, in 60-lb. cans (2 in a box), 6@7. We could handle to advantage a quantity of No. 1 comb honey; also pure beeswax at 22@25.

R. K. & J. C. FRISBEE,
Denver, Col.

CHICAGO.—Honey.—We report our market well cleaned up on fancy white comb honey in 1-lb. sections. A neat package and a fancy article would sell quickly at 14c. No. 2 comb, or dark, would not sell at over 10@11. We report better inquiry for extracted, at 5@7, depending on quality. Beeswax selling at 30c.

S. T. FISH & CO.,
189 South Water St., Chicago, Ill.

CHICAGO.—Honey.—During this month a good movement has been felt in the market. Sales have been of small lots each time but sufficiently frequent in occurrence to make the aggregate sales of some volume. White comb of the best grades, 14c; travel-stained or off in color, 13@13½; yellow comb, 10@11; dark, 7@9. Extracted, 5½@7, according to flavor and package; 60-lb. cans of white bring the highest price. Beeswax, 28@30.

R. A. BURNETT & CO.,
163 So. Water St., Chicago, Ill.

DETROIT.—Honey.—Best white comb 14@15; supply moderate. Darker grades, 11@13. Extracted, 6@7. Beeswax in good demand at 28@29.

M. H. HUNT,
Bell Branch, Mich.

PHILADELPHIA.—Honey.—The supply of comb honey is getting low in this market, with considerable call; selling at 11@14, as to quality. Extracted honey in fair demand and good supply at 6@6½c.

WM. A. SELSER,
10 Vine St., Philadelphia, Pa.

BUFFALO.—Honey.—The honey market is getting well cleaned up; fancy exceedingly scarce, selling readily at 13@14; choice, 11@12; commoner grades, 8@9; buckwheat very slow and dull at 8@9.

BATTERSON & CO.,
Buffalo, N. Y.

ALBANY.—Honey.—There has been an unusual demand for both comb and extracted honey since the beginning of Lent, and we have but very little of either now on hand. We would advise parties still having honey to dispose of to forward it at once.

CHAS. McCULLOCH & CO.,
Albany, N. Y.

KANSAS CITY.—Honey.—The demand for comb and extracted continues fair. We quote No. 1 white 1-lb. comb, 14@15; No. 2, 12@13; No. 1 amber, 12@13; No. 2, 10@11; extracted, 4½@6½. Beeswax, 22@25.

C. C. CLEMONS & CO.,
Kansas City, Mo.

KANSAS CITY.—Honey.—The stock of comb honey is large; market well supplied. Fancy white 1-lb. combs, 14; amber, 12. Receipts of extracted light; white, 7; amber, 5½@6; Southern, 4½@5. Beeswax, 22.

HAMBLIN & BEARSS,
Kansas City, Mo.

CLEVELAND.—Honey.—Honey remains at about the same price as in our last quotation. Parties are buying sparingly, and we quote No. 1 fancy 1-lb. sections at 13@14; No. 2, 11@12. White extracted, 6@8. Beeswax, 28@30.

WILLIAMS BROS.,
80 & 82 Broadway, Cleveland, O.

CINCINNATI.—Honey.—There is a fair supply of extracted and comb honey, while demand is slow. We quote extracted honey at 4@7 on arrival. Comb honey, 13@16 in the jobbing way. There is a good demand for beeswax at 25@28 for good to choice yellow.

CHAS. F. MUTH & SON,
Cincinnati, O.

BOSTON.—Honey.—Our market on No. 1 white comb honey is well cleaned up, and it is wanted. Price for comb, 13@14; extracted, 5@6.

E. E. BLAKE & CO.,
Boston, Mass.

Closing out balance of my fine extracted basswood honey at 7c f. o. b. Who is not supplied?

ELIAS FOX, Hillsboro, Wis.

ALFALFA HONEY. very white, thick, and rich. Two 60-lb. cans at 7c. Same, partly from cleome (tinted), 6c. Samples, 8c.

OLIVER FOSTER, Las Animas, Col.

We yet have extracted alfalfa at \$7.80 per box of 120 lbs.

AIKIN BROS., Loveland, Colo.

BEEWAX WANTED.—Will pay 31½c cash for absolutely pure beeswax that will stand chemical test. Write me at once.

CONVENTION NOTICES.

The semi-annual meeting of the Southern Minnesota Bee-keepers' Association will be held on the first Monday in May, 1895, at La Crescent, Minn. All bee-keepers are invited.
E. C. CORNWELL, Sec., Winona, Minn.

Wants or Exchange Department.

Notices will be inserted under this head at one-half our usual rates. All advertisements intended for this department must not exceed five lines, and you must say you want your ad't in this department, or we will not be responsible for errors. You can have the notice as many lines as you please, but all over five lines will cost you according to our regular rates. This department is intended only for bona fide exchanges. Exchanges for cash or for price lists, or notices offering articles for sale, can not be inserted under this head. For such our regular rates of 20 cts. a line will be charged, and they will be put with the regular advertisements. We can not be responsible for dissatisfaction arising from these "swaps."

WANTED.—Old combs in frames. *Describe*, with price. W. L. COGGSHALL, West Groton, N. Y.

WANTED.—To exchange the only wax-extractor in the world that will extract all the wax from old combs rapidly by steam, also bee-smokers, for wax. C. G. FERRIS, South Columbia, Herk. Co., N. Y.

WANTED.—To exchange Universal wood-worker, one groover, one dovetailer, and one cutter-head table; also short jointer, all in good order. What have you to trade for one or all?
W. S. BELLOW, Ladora, Ia.

WANTED.—To correspond with parties wishing to sell or test my new hive. F. DANZENBAKER, 1110 New York Ave., Washington, D. C.
Reference, GLEANINGS.

WANTED.—25 to 100 hives of bees. Who can furnish them the cheapest? I will exchange, for bee-hive machinery, queens bred from a straight five-banded breeder valued at \$50, or from imported stock.
H. G. QUIRIN, Bellevue, Ohio.

WANTED.—To exchange 200 colonies of bees for any thing useful on plantation.
ANTHONY OPP, Helena, Ark.

WANTED.—To exchange Black Minorca eggs at 60c per 15 for a few untested queens.
H. BARBER, Adrian, Mich.

WANTED.—Bees, bee-supplies, and poultry, in exchange for strong, well-rooted basswood-trees. This is the time to transplant.
W. R. LIGHTON, 601 N. Y. Life Bldg., Omaha, Neb.

WANTED.—To exchange yellow Italian queens the coming season, also the best varieties of strawberry-plants, cheap, for foundation or offers.
MRS. OLIVER COLE, Sherburne, Chenango Co., N. Y.

WANTED.—To exchange bees, queens, and eggs (from B. P. Rocks, S. C. B. Leghorn, and Light Brahmas), for bee-supplies or offers.
CHAS. H. THIES, Steeleville, Ill.

WANTED.—To exchange several good safety bicycles. Honey wanted. Send sample.
J. A. GREEN, Ottawa, Ill.

WANTED.—To exchange Australian stamps for any other denominations. Send along from any part of the world, and I will return equivalent.
H. L. JONES, Goodna, Queensland, Australia.

WANTED.—To exchange 6 and 12 inch Root foundation-mills for wax, honey, or offers.
I. J. STRINGHAM, 105 Park Place, New York, N. Y.

WANTED.—20 lbs. of bees and 10 tested queens in exchange for Gregg raspberry-seeds.
H. H. AULTFATHER, Minerva, O.

WANTED.—To exchange Foxhound pups, peerless stock, for any thing useful. Fox terrier wanted.
S. S. MILLER, Grantville, Md.

WANTED.—To exchange raspberry and blackberry plants, \$6 per 1000, bees \$5, Japanese buckwheat, for beeswax. A. P. LAWRENCE, Hickory Corners, Mich.

WANTED.—To exchange poultry and eggs (3 best kinds) for thin foundation, sections, shipping-cases, or new smokers.
D. F. LASHIER, Hooper, Broome Co., N. Y.

WANTED.—To exchange supplies and other goods for honey. O. H. HYATT, Shenandoah, Iowa, 20tf

3=Banded ITALIAN Queens, from my own imported queens, \$1.00 each.
Max Brauer, Beeville, Bee Co., Tex.

WHY NOT

Send your orders to W. H. Laws for Italian Queens?

THE BEST IS THE CHEAPEST.

For beauty and business you can't beat them. The leading bee-keepers of the U. S. are my customers, and all praise them. I breed either the Golden or Leather-colored strains.

PRICES REDUCED

To suit the times. Fine breeders always on hand, \$2 to \$3. Untested, 75c; 3 for \$2. Tested, 1; 6 for \$5. Address

W. H. LAWS, LAVACA, ARK.

«MONEY-MAKERS»

Are a strain of business Italians that winter in the cold North, and are ready for business, with a bushel of bees, when the flowers bloom. They are gentle and industrious. Queens warranted purely in June. Each, \$1.00; six, \$5.00; doz., \$9.00. Safe arrival and satisfaction guaranteed. Never had any disease.

Address E. F. QUIGLEY, UNIONVILLE, MO.

A Bargain.

I have a complete set of the back numbers of GLEANINGS, unbound, clear up to the present, that I will sell for \$10. Regular price, bound, \$25.

MRS. A. A. RICE,
Seville, Ohio.

3 Great Potatoes. Read Your Catalogue.

That great Carman No. 1 (10 lbs. grew 24 bushels); Maule's Irish Daisy; and Everett's Onward (new); all three mailed, 50c (large, \$1). ¼ bu. each of Puritan, Rural New-Yorker No. 2, American Wonder, and Everett's Early Six Weeks, with 1 lb. your choice, \$2.00. Last four named, \$3.00 per barrel.

Smith's Stock and Seed Farm,
Padelfords, N. Y.

SPRAY • PUMPS • AND • SPRINKLERS.

A Complete Line for Large and Small Growers, at Prices Within Reach of All.

Fig. 1.
Price \$3.25.

It is becoming every year more evident that, in order to secure perfect fruit or foliage, it is absolutely essential that the trees and shrubs be sprayed with poisonous arsenites one or more times each season at just the right time in order to kill the insect pests which work so much havoc. If you would secure a crop of salable fruit, spraying is as necessary as the proper cultivation and enriching of the soil. To do this work most easily and economically you require the best tools to work with. We have carefully examined many spraying outfits, and believe the line we offer here can not be surpassed in quality, efficiency, and price.

Fig. 3.
Myers nozzle.

Bordeaux Vermorel.

The Myers Bucket Brass Spray-Pump is shown in Fig. 1. It includes 4 ft. of $\frac{1}{2}$ -inch hose and Myers spray and sprinkler nozzles as shown. The Vermorel or Bordeaux nozzles may be had instead of Myers, when specified, at 25c each extra. These nozzles are shown half size in Fig. 3. The Myers is the simplest and least liable to get out of order. The aperture in the Bordeaux can be varied in size from the finest spray to a stream. The degorger in the Vermorel is very handy for clearing the spray tip of any obstruction. The Myers is regularly furnished on the bucket pump, Fig. 1; the Bordeaux on the knapsack, Fig. 2, and the Vermorel on the barrel pumps, Fig. 7, unless otherwise ordered.

Fig. 2.
Knapsack Spray Pump.
Price \$6.00

These spray nozzles throw a spray as fine as mist, so that it floats up like a cloud, settling on the foliage like dew. This is more effective, and uses less than a fourth of the liquid required in using a perforated nozzle.

The bucket pump, Fig. 1, is the same

Fig. 6.

Price List of Nozzles.

Myers spray tip, 35c; sprinkler 35c.
Male end or hose connection, 25c.
8-foot pipe extension, 35c.
 $\frac{1}{2}$ -inch hose, 10c per foot.
Bordeaux nozzle, 60c.
Vermorel nozzle, 60c.

Fig. 5

as we have sold for several years, but improved in finish, and reduced in price. It is made entirely of brass, with rubber ball valves; has an air-chamber making a continuous spray; and a steady pressure of 50 lbs can easily be maintained. A fine jet is discharged from the bottom to keep the solution thoroughly mixed. By unscrewing the nozzle you can throw a stream, and thus use the pump for washing windows, bugies, etc. Fig. 6 shows the manner of operating the pump with pipe extension, which is necessary to reach all parts of the tree from the ground.

Knapsack Spray-Pump. This is shown in Fig. 2. The can is of galvanized iron, and holds 5 gallons. The pump is the same kind as the bucket pump, but made shorter. It may be entirely removed from the can, and used as a bucket pump if desired. It is the only knapsack having an agitator to keep the solution stirred. The lever handle may be changed to use

with either hand, and one of the straps having a snap may be passed across the top, and hooked, forming a bail to carry the can by. As regularly sent out, it includes Bordeaux nozzle on 2 ft. of pipe extension and 5 feet of $\frac{1}{2}$ -in. hose; can be furnished with copper tank at \$3.60 extra. Vermorel nozzle substituted at same price, if so ordered.

Fig. 4.
Fountain Sprayer.
Price \$3.25.

Fountain Sprayer. Fig. 4 shows this valuable instrument, and its manner of use is shown in Fig. 5. It is the same in principle as the Lenox sprayer, on this page, but is made neater and more substantial. The most convenient implement for potato vines and small shrubs. Price \$3.25. Extra tube bulb and rose furnished for \$1.20.

Myers Barrel Spray Pump.

Where you have a larger amount of spraying to do, you can accomplish it more easily with an outfit of this kind. It has our patent submerged cylinder, is double-acting, has patent expansion rubber bucket, has a large air-chamber to cushion the spray, is provided with TWO DISCHARGE PORTS, one or both of which can be used for spraying. It has steel pins, brass plunger cylinder, and brass-lined lower cylinder, good leverage, is very powerful, and easy to operate, will throw a spray as fine as mist over any ordinary fruit-tree, and will throw a solid stream 60 feet from the point of the nozzle.

This can be mounted either on the side or end of a common barrel. The barrel may be mounted on wheels; or, if you have a horse to spare, it can be drawn around under the trees in a wagon or on a stoneboat. This outfit includes vermored nozzle, the same as the bucket pump, and the pipe extension can also be used, if needed, for high trees. We can furnish the outfit, as shown, without the barrel, consisting of pump with three feet of suction pipe, strainer, and agitator, 5 feet of rubber hose and vermored nozzle, with extra tip, for \$7.00; or the same with two 5-foot lengths of hose and two nozzles, for \$8.00; 8-foot extension, at 50 cts. extra.

We are prepared to furnish the Myers Knapsack Sprayer, with copper tank, complete, for \$9.60; and the Myers Hydraulic Spray-Pump, large enough for the largest growers, for \$22.00. Our space is too limited on this sheet to do more than mention these two items. If any are interested we will gladly mail circular with full description and illustration on application. This circular contains two pages telling what mixtures to use for different crops, and when to spray. One of these circulars is included with all the Myers pumps we furnish. It contains fuller descriptions of all the foregoing spray pumps.

Smith's Novelty Force-Pump.

sold for many years. Four nozzles are included with each pump as shown. No. 1 for upward stream, 2, for horizontal stream for washing buggies, windows, etc.; 3, for watering and spraying plants and flowers, and 4 for spraying trees. This is a strong pump, made of tin, with wood plunger, and will throw a stream 30 to 40 feet high. Price \$1.00; 12 for \$10.00; 24, \$18.00; 36, \$25.00.

Common-Sense Spray Pump.

working. The piston, or plunger, is worked with a lever handle, giving greater force for the same power exerted. The plunger-tube is shorter, and larger in diameter, than the ordinary pump. If the water comes over the top it spills right into the pail again.

It has an air-chamber, with valve, giving a continuous stream or spray. It has a short rubber hose to give direction to the stream or spray, without moving the pump. It has also an adjustable nozzle for stream or spray. We are able to offer them for only 60c each, or \$1.00 postpaid. In quantities the price will be \$6.00 per doz.; 3 doz. for \$16.00. Larger quantities quoted on application.

The Lenox Sprayer.

In Fig. 11 we show one of the most convenient implements we know of for applying poisons to potato-vines and other small plants and shrubs. With this the work can be done with greater ease and speed than you would think possible. You can spray as fast as you walk. No waste, because by releasing the pressure of the thumb the spray stops instantly till you direct it toward the next vine. Price of Lenox Sprayer, complete, with tank to hold 22 quarts, \$3.00. The sprinkler rose with bulb and hose, no tank, \$1.20. Post. 15c.

The Lenox Atomizer.

In Figs. 12 and 13 we show the Lenox Atomizer, a very handy implement for various uses. For sprinkling clothes, or watering plants in the window, you use pure water.

For applying poisons, you use any of the solutions of London purple, Paris green, hellebore, pyrethrum, according to the insects to be banished. For convenience you want an extra rubber ball for the poisons. It uses the liquids with such economy that a pint bowl of solution may be made to go over a very large surface. It is recommended for bugs and insects on carpets, furs, or clothes. For this purpose a carbolic acid solution is used. Price 35c each; post. 10c. Extra rubber balls, 15c.

PRICE
\$7.00.

Advertising

type, and have thus had an opportunity to study the effect of different combinations of type in displaying advertisements. If an advertisement is sent to the REVIEW I will do my best to set it up in an effective manner. If desired, I will also compose the advertisement, the advertiser sending me his catalog, or, if he has none, giving me the strong points to be made in favor of his business. I also offer my services to those who do not advertise in the REVIEW. I have a good assortment of type, borders, ornaments, etc., and shall be glad to submit proof of my efforts in composing and displaying advertisements. Send me your circular, and I will send proof of an ad., and put a price upon the work if it should be accepted. As a specimen of my work in this line, see the ad. of W. W. Cary, in this issue of GLEANINGS.

W. Z. HUTCHINSON, Flint, Mich.

STRAY STRAWS

FROM DR. C. C. MILLER.

ILLINOIS STATE FAIR offers bee-keepers \$255, in premiums of \$2 to \$20 each.

GUENTHER says Italian queens don't live as long as black ones.—*Bienen-Vater*.

THE FIRST PAGE of the *American Bee Journal* for March 7 is well edited. Five editors appear on it.

PROPOLIS, warmed and applied as a plaster to corns, is said to be a cure, in *Schweizerische Bienenzeitung*.

BEES FLEW a little, March 18, with the thermometer at 34°, and flew nicely at 44°; but the sun shown brightly, and the air was still.

IN ITALY an enemy of the wax-worm has been discovered—a fly that lays its egg in the worm, from which grows a larva $\frac{1}{2}$ inch long that kills the worm.

LE PROGRES APICOLE occupies a supplement of 15 pages telling about a four-days' bee-keepers' convention and exposition, with 184 prizes, commencing Aug. 31 at Mons, Belgium.

IN BUYING SEEDS of honey-plants, look out you don't get a start of bad weeds. A lot of sweet-clover seed that I bought gave me a start of three bad weeds I had not known before.

"How OLD may brood-combs be before changing them?" is a query in *A. B. J.* No one of the repliers thinks of changing them before 10 years, and the large majority never change on account of old age.

ACTINIDIA POLYGAMA is mentioned as a new honey-plant in Germany—a twining plant, perfectly hardy, bearing long clusters of green fruit that is of the size of gooseberries; sweet, and with the odor of pineapples.

A BEE'S EGG, according to some authorities, weighs .00013 of a gram; according to others, .00021 of a gram. Can Hasty or some one else tell us which is correct? [Hens' eggs vary in size; and, if my eyes have not deceived me,

queens' eggs. That being the case, both figures may be right.—Ed.]

BLACK BEES seem to be preferred to Italians in England, but in Australia not. In the Question-box of the *Australian Bee Bulletin*, all the repliers strongly preferred Italians except one man, and he had had only one colony of Italians.

E. E. HASTY, in *Review*, and "Gleaner," in *American Bee Journal*, seem to spend a large part of their time nosing around in the pages of GLEANINGS after choice bits. All right, brethren, there's nothing wrong in your brouseing where you find the best picking.

NO WONDER beeswax was in demand in the Middle Ages. I read in *Elsass-Lothringischer Bienen-Zuechter* of the immense number of wax candles burned in the churches. In one of them, 16 candles, each weighing 30 pounds, were kept burning day and night.

HASTY SAYS, in *Review*, that "putting foot-notes of the GLEANINGS variety on the Straws" gives vivacity to the first page. So say I. They're more interesting reading to me than the Straws themselves. [Don't believe it; but I'll stick 'em on so as to have my say.—Ed.]

"WE HAVE ALWAYS found bees build burr-combs when starters only are put in the upper story."—*Australian Bee Bulletin*. Never thought of it before; but it's reasonable to suppose burr-combs will be worse with small starters, because the bees are slower about going up.

GIANT BEES of India, or *Apis dorsata*, are now advertised, and I'm afraid there is something wrong. The advertiser says one of the drones put in a cage with a black or Italian queen will fertilize her at once, "and will fertilize as many as four queens before he stops"! [See Editorials.—Ed.]

CHEMISTS SAY there is more "sweetenin" in a dollar's worth of white than in a dollar's worth of brown sugar. I never disputed it, but I'd just like to know how it can be. Take a barrel of brown sugar and change it to white, and then it costs more, doesn't it? But have you added any sweetness to it?

"CLUMSY" or no clumsy, if you can make on rolls foundation like the Given, that the bees will like as well as that made with the press, I want to try it. I want foundation, not for its beauty, but for the beauty of the finished product. [We can make the article; and if the bees or their owners can tell it from the pressed wax, they are smart ones.—Ed.]

THE *Bienen-Vater* is an excellent German bee-journal, published at Vienna. You can subscribe for it at a dollar a year, or you can join the bee-keepers' society, paying 50 cents a year, and get the journal for nothing. Is it any wonder the society has a large membership? I tell you, those Germans can give us points on bee-keepers' societies.

A VENERABLE TRADITION has come down to us, that allowing bees to get started storing in the brood-nest seriously interferes with their storing in supers. I've bowed to that idol long enough, and now stand up to say I don't believe there's a word of truth in it. So there, now! [I am half inclined to think the doctor is right. If there is a supporter of that "Venerable Tradition," let him speak out.—Ed.]

"A NICE JOKE" is what Mr. Cowan calls that Straw on p. 123 about British honey production. That Medina printer wouldn't think it any joke if I could get hold of him. Only I'm afraid the mistake was mine instead of his. You see, I gave 5250 lbs. as the possible production annually, when I meant tons. But Mr. Cowan thinks 10,000 tons would be nearer the mark. [Your treat, doctor.—Ed.]

PROPOLIS, says Geo. W. Stephens, in *A. B. J.*, can be cleaned off the hands with soap and water alone. "Use plenty of soap and not much water; rub the hands together in the lather until the propolis is dissolved, then wash in the water. If any propolis yet remains, lather and wash again." [Grease the fingers with vaseline before working with the hives, and the propolis won't get on the fingers much if any.—Ed.]

LA GRIPPE, says Dr. Peiro, in *A. B. J.*, can generally be shaken off if taken at first. "Absolute quiet in a warm bed, not a thing to eat for 24 hours, and only hot buttermilk to drink—all you want of it. After that time, toast, with the yolk of a soft-boiled egg three times a day is permissible. In a few days you will be quite able to resume your regular work and diet." [Dr. P. is about right. I have been testing that sort of advice, without the buttermilk, and it worked tiptop. We don't have buttermilk at our house.—Ed.]

WHAT'S THE RIGHT ANSWER to R. C. Aikin's demand, p. 205, for 25 and 50 lb. cans for extracted honey instead of 60 lbs.? [Yes; but we can't make the large manufacturers change. The 60-lb. cans are made to hold a great variety of liquids, among which kerosene and lubricating oils are the most prominent. These

goods are sold by the gallon; and the cans hold, even measure, five gallons. A four-gallon can would be an odd-size; and as the honey interests are insignificant compared with the oil-trade, it is evident that the smaller size, holding 50 lbs., would cost as much as or more than the 60-lb. size. The square cans are cheap because the oil and syrup business makes them so, and we must take the regular size or pay more.—Ed.]

[As this item, although by another writer, properly belongs to this department, I put it here at the end.—Ed.]

Dr. Miller's criticism in March 15th GLEANINGS, in *Stray Straws*, is a little misleading when he compares the capacity of my hive with 9 frames with that of the Dovetailed hive with 8. My statement, that I favored the eight-frame hive with 9 frames, applies as well to the eight-frame Dovetailed hive as to mine or any other of same width. Comparing them both as an eight-frame hive will be fair. And, again, if Dr. Miller will think just a moment he will be able to see (without getting off the fence) that adding an extra frame does not increase the capacity of the hive except in one respect. It gives more comb surface, but makes the combs thinner and only increases the capacity for brood, and actually diminishes the capacity of the hive in other respects. It diminishes the room for bees by just the space occupied by the extra comb. It diminishes the holding capacity for stores, as it adds an extra empty bee-space.

Mr. Hatch has made the same criticism on p. 225 of the same issue. My brood-frame has a cross-bar in the middle, which has been overlooked in the estimate of the comb-space in it. This was omitted in my article also.

H. R. BOARDMAN.

East Townsend, O., Mar. 18.

[There! you have struck the key to the situation exactly. I thought I was right, but couldn't prove it quite as well as you have done.—Ed.]

THE OLD-STRAW BEE-HIVE.

THE BEST FORM FOR A HIVE.

By H. R. Boardman.

This has always seemed to me to be a model of perfection not surpassed by any other hive in use to-day, if man's convenience is eliminated from the question. This strange, ancient hive, was hardly the result of accident, but was, I think, the result of careful study of the requirements of the bees by the pioneer bee-keeper, who took the dimensions of the swarm, as it were, for an economical covering for their protection. It is most perfectly adapted by its

shape to fit and protect a swarm of any size, large or small, and that, too, without the use of division-boards.

There are two important features to be secured in the construction of a bee-hive—the requirements of the bees and the convenience of the bee-keeper. It becomes important to decide how far we can afford to sacrifice the one to secure the other. A plain box or chamber, affording a cavity of sufficient size, is all that is required by the bees for a domicile. They will store as much honey in a log gum or a straw skep as in a hive of modern pattern. Even movable frames, that have become an indispensable feature of modern bee-keeping, are not appreciated by the bees. I have more than suspected that a plain box hive, of the old type, with the combs built securely to the sides and top all around, furnishes better conditions for wintering than the modern movable-frame hive.

In buying bees to transfer, I sometimes used to get an old neglected movable-frame hive. The frames would be irregularly spaced, and the combs built crosswise in every conceivable shape. I soon learned that they were not as valuable for my use as the plain box hives. I have never been able to see how these improvements furnished any of the requirements of the bees, or conveniences to the bee-keeper. There are a great many of these primitive bee-keepers all over the country, who will have from one to half a dozen colonies of bees, kept in this way. They buy improved hives and fixtures, but never expect to look into a hive after the bees are put in. It pains me to see my poor neighbors pay their money out for something that will do them no good, and I am inclined to recommend only box hives for box-hive bee-keepers.

THE BEST FORM FOR A HIVE.

I am aware that bees adjust themselves to a very wide range of circumstances, and even to serious inconvenience in the hives they sometimes occupy, without seeming to materially affect the results. I am sure that this furnishes no proof that there is not an economical form for a hive, that will give better results than any other form. I am aware that there is no such fixed form generally recognized among bee-keepers; but the size and shape of hives, in use varies through a very wide range, and are, I am well satisfied, many of them at least, the result of accident rather than the careful consideration of the requirements of the bees or the convenience of the bee-keeper. I have never been able to find any sensible reason why a hive in cubical form, with a square frame, was not the most perfect form. It furnishes, more nearly than any other, the natural requirements for a brood-chamber in permitting a round, compact brood-nest, and at the same time it furnishes the most economical form for the convenience of the bee-keeper.

Such a hive I have used for many years. Before the advent of the one-pound section I used a deep frame, but it was not just square, but deeper than wide. This gave good results; but I wished to use wide frames in the regular hive-body, for holding sections. Accordingly I made a slight change in the dimensions of the hive, which enable me to use my present square frame. The hive in most general use, and the most popular, perhaps, of all, is the long shallow hive of the old Langstroth pattern, with its improvements and modifications. I wish to compare these two forms of hives in some of their important features, and for convenience will call them the square hive and long hive.

SOME OF THE ADVANTAGES OF A SQUARE HIVE.

First, in the construction it is the most economical form, giving greater holding capacity than any other. Any one who can make figures can convince himself of this if he is interested enough to make a careful comparison of the square and long hive. It affords the same economy in construction, and it also gives less surface exposure to the cold of winter and the heat of summer, which is an item of more importance than might at first appear.

When I took up my pencil and made a careful computation of the comb capacity of the square and long frame, I was not a little surprised to discover that the square frame ($12\frac{3}{4} \times 12\frac{3}{4}$) actually contained the most comb space. The compact form of the square hive, giving the least possible surface exposure, and at the same time giving a brood-nest of the best possible form to resist cold, contributes largely to the best results in wintering. It has a reputation for good wintering qualities that few will think of questioning. The same features that make it favorable for wintering are also favorable for spring management. There is no place where these favorable conditions are more appreciated by the bee-keeper than in the spring.

There is not much in the claim that the long shallow frame has a decided advantage in manipulating; as the square hive has, if conveniently constructed, a side opening that makes the frames easy of access. There is, though, one advantage in a shallow frame—a prominent one—which I will not fail to recognize. It spaces more uniformly at the bottom of the frames. If fixed frames are used, of course this advantage all disappears.

There has been some discussion in the past over the height of the hive for the best convenience for yard work, and I regard it a matter of some importance among other features of the hive. The square hive furnishes the best height for convenient work possible, in sitting at a single hive or standing when tiered two stories.

Among the many who have discovered that the long hive is not a model of perfection is

John Craycraft, in *GLEANINGS*, p. 47. He gives some very sensible arguments, showing the advantages of his square hive over the long hive, although his is not a square frame. This, to my mind, eliminates the most objectionable feature. His experience with both styles of hives entitles his views to careful consideration. It has often occurred to me that I should want to use the frames as he arranged to use them, the short way of the hive, if I were using the long hives. Nor would this make a hive that I could be satisfied with by any means.

HOW THE SQUARE HIVE OPERATES IN WINTER.

At the beginning of cold weather the brood will all be hatched. This will leave the lower part of the combs empty, upon which the bees will be clustered. The stores will all be above the bees, in the most favorable position to be protected and preserved by the heat ascending from the cluster. As the winter advances, the consumption of stores enlarges the brood-nest of empty comb, and the cluster advance slowly upon the stores above them; and as long as any stores are left they are in an available position, and preserved in good condition for use. This is important. Stores of honey exposed for any considerable time to the cold become candied or grained, and are seriously impaired, and sometimes they become utterly worthless, and will be dug out of the comb, and carried out of the hives when warm weather comes. At the approach of spring, the cluster will have reached the top of the combs, where brood-rearing will begin in the warmest and most favorable part of the hive.

HOW THE LONG HIVE OPERATES IN WINTER.

Long before winter is over, the stores will be exhausted above the cluster to the top of the frames. If the cluster was located in the center of the hive, they will now have the stores divided into two lots, one in either end of the hive. One lot must now be abandoned while they advance upon the other. When these are consumed they are hopelessly cut off and separated from the stores in the other end by the empty comb between, and will perish unless a fortunate warm spell comes to their relief. But suppose the cluster is located at one end of the hive, at the beginning of winter. The stores will all or nearly all be at one side, and exposed to nearly as much cold as if no bees were in the hive at all. If the cold is severe and continuous throughout the winter, how could any thoughtful bee-keeper hope or expect the dormant cluster of bees to advance upon this frozen and candied mass of stores, and be able to appropriate them for food, with much chance of survival?

The large amount of surface exposure of the long hive makes it unfavorable for wintering without protection. This fact seems to have been early recognized by its advocates, and chaff packing as a winter protection came to the rescue. By this improvement the hive

that was already clumsy and awkward to handle became practically an immovable fixture in the bee-yard, and manipulation of such hives was not to be thought of.

I think the chaff hive has hardly been regarded with favor by the majority of large honey-producers, even by those who practice outdoor wintering. The manipulation of hives is too important a feature to be sacrificed for the advantages thus gained.

East Townsend, Ohio.

E. FRANCE'S QUADRUPE LANGSTROTH HIVE.

HOW USED AND MADE BY HIMSELF.

By E. France.

First, we will say our lumber is dressed on both sides, and is $\frac{3}{8}$ inch thick. We want a pair of good match planes that will make a good tight job. For an eight-frame hive, match boards together for a bottom 30 inches wide by $42\frac{3}{4}$ inches long. We now want a division-board 30 inches long, $9\frac{1}{4}$ inches wide. Make the division-boards double thickness; nail two pieces of lumber together flatwise. Now rabbet out of the top edge of the division-board $\frac{1}{2}$ inch out of the thickness of the board, and $\frac{5}{8}$ inch down toward the bottom. Cut a rabbet on both sides of the division-board. Those rabbets are to hold up one end of the frames. Now put the division-board across the bottom-board, exactly in the center, and nail it fast, driving the nail through the bottom-board into the division-board.

Now make two short division-boards, double thickness, to go lengthwise of the bottom, dividing the hive into four equal parts. Nail them in, and we are ready for the sides, which should be wide enough to come even with the top of the division-boards and down to the bottom of the bottom-board ($10\frac{1}{2}$ inches wide); now two boards the same width to go across the ends; then we want some one-inch hoop-iron. Cut off a piece 30 inches long. Round off the two upper corners, then drive the iron into the division-board between the two thicknesses. Drive it in half an inch, leaving half an inch above the division-board. Now cut two pieces of hoop-iron to go into the short divisions, the same length as the division-boards. This iron is for a safeguard to keep the bees from passing from one colony to another over the divisions, in case the honey-board should be warped enough to let bees pass over.

We want quite a lot of $1\frac{1}{2}$ -inch strips, same thickness as the hive lumber. Place a $1\frac{1}{2}$ -inch strip around the top of the hive, $\frac{1}{2}$ inch down from the top. This is for the top chamber to rest on.

If you now look at the pictures you should get a good idea of the hive. The entrance is put at the corner furthest from the center of

the hive. The bees in winter cluster about the center of the hive, away from the entrance. The open hive shows the large entrance open for summer. The closed hive shows the large entrances, $1\frac{1}{2}$ in., closed by the button, down to the small hole, $\frac{1}{2}$ inch for winter. The closed hive also shows the ten-inch belt, as we have them in summer, when the third stories are on. The belt is in two parts, hooped together. When we open the hive, one-half of the cover is turned over on to the other half. We can then work two colonies, can take off one-half of the belt, and all the loose stories, if we wish. If we want to get into the lower story, or brood-nest, when we are done with

ting in the half-inch lining, take the square block (that you see upon the open hive), four inches square, $1\frac{1}{2}$ inches thick, and put it in between the outside of the hive and the half-inch lining. Make the hole match with the hole through the hive; nail through the half-inch lining into the block; pack chaff around it. For those bottom entrances, cut out half of the thickness of the bottom part of the cushion frame, opposite the holes in the side of the hive; also see that there is a passage through the half-inch lining. Those loose parts for second and third stories are made with a cushion in one end and one side. Make them the right size to fit one of the quarter-

FRANCE'S QUADRUPLE LANGSTROTH HIVE, CLOSED.*

the two colonies, we can put on the loose stories and the half belt, then shut down the cover; then if we want to work the other two colonies, just turn over the other half of the cover or chamber, and work the other two colonies. In winter we take off the third stories and the belts, and pack them away in the storehouse.

There is a two-inch lining inside the hive. All around the outside we use the $1\frac{1}{2}$ -inch strips to make a frame; nail the frame to the hive, then side up inside the hive with $\frac{1}{2}$ -inch lumber; fill the vacant space with chaff, well packed in. When lining up the end chaff-box, leave the half-inch lining low enough to form a rabbet to rest the end of the frames on, as shown in the cut. There must be a bee-passage through the chaff lining. Bore a hole through the outside of the hive; then when you are put-

divisions of the main hive. Rabbet out a frame-rest from the single-board end. The rabbet at the cushioned end is made by leaving the half-inch lining down $\frac{3}{8}$ of an inch. Make these upper stories $9\frac{1}{2}$ deep. I use a solid board (honey-board) over these hives, made to fit one division or quarter-section; cleat at the ends to keep them from warping. Honey-board is shown in the cut, up in the turned-back cover, with two holes through it, holes covered with wire screen. The holes are used for feeders. When I have to feed I set one of my pepper-box feeders over each hole.

Now for the roof, or top chamber. The cut shows how they are made. We want them

*The camera has distorted the true rectilinear lines a little in the hive and building in the background, for which allowance should be made.—ED.

deep enough to cover one set of upper stories, and leave room above the honey-boards for some straw packing for winter. The gable-end boards in my hives are $17\frac{1}{2}$ wide at the ridge, below the roof-boards, and $13\frac{1}{2}$ in. under the eaves. The roof is hinged together with three heavy 5-inch strap hinges. My frames are L. size, $17\frac{3}{8} \times 9\frac{1}{8}$.

Now I believe the hive is made. You can see very nearly what kind of a stand I set it on—6 stakes driven into the ground, 2 feet four inches out of the ground; 3 boards, 4 inches wide, nailed on top of the stakes crosswise of the hive, all leveled with a spirit-level.

My bees are wintering finely in those hives this winter—140 colonies; not one yet dead. All had a good fly Feb. 27.

an hour or two, then smoke them a little and put in the upper set of frames fixed to suit you; or if the swarm is small, drive the bees down into the lower story, and put the honey-board on that.

I find this hive safe to winter bees in. Wind doesn't blow it over; farm stock don't push them over.

One thing I forgot to mention. That single story, shown with the open hive, shows a strip of galvanized iron nailed on the single side, raised up $\frac{1}{2}$ inch above the wood. That should go around the single end also. It is put on as a safeguard to prevent the bees from passing over from one colony to another. We cut a strip $1\frac{1}{2}$ inches wide, and long enough to go around one side and one end; nailed on the

FRANCE'S QUADRUPLE HIVE OPENED AND DISSECTED.

Some one says, "How in the world can you hive a swarm in that thing?" Easily. First, hive your swarm in a common box hive; then turn up one half of the roof over on to the other half. Put your frames into the lower story containing combs, or foundation or starters; set on the second story empty, no frames; have the honey-board ready to put on. Now get your box hive that has your swarm in it; bring it to your prepared quadruple hive; hold your box hive over the empty second story of the frame hive—box hive open end, of course. Now give the box hive a good chug down on the frame hive, and your bees are all in. Put on the honey-board quick, then let them alone for

honey-board; and other single stories fit right in there. The iron is not in the way at all.

Platteville, Wis.

[It may be a little difficult to understand the exact construction of the quadruple hive from the description; but if you will examine carefully the engravings I think it will be plain. It will be seen that these quadruple hives are large, and it would almost appear that they are clumsy, and would require clumsy and difficult manipulation. But friend France has got the handling of them down to a science. When I saw him work them he did nothing with them except what any frail woman could have done. Indeed, although he is over 70 years old he handles one yard entirely alone, taking large crops of honey. My purpose in saying this of the quadruple hive as used by Mr. France is

not to boom it nor to say that everybody should use it, but only to show that it is not such an awkward hive as it appears to be.—Ed.]

THE MADISON CONVENTION.

REPORT OF THE ELEVENTH ANNUAL CONVENTION OF THE WISCONSIN BEE-KEEPERS' ASSOCIATION, HELD AT MADISON, FEB. 6 AND 7, 1895.

By H. Lathrop.

It was with some misgivings that the officers of our association wended their way to the State Capitol to our regular annual meeting. For some years past the attendance had been getting smaller; and just at convention time this year there occurred one of the most severe storms of the winter, which would discourage some from coming. But the outcome was the reverse of what we feared. There was a good representation of the old standbys, and a number of bright young men who attended for the first time, and who will doubtless be among the future successful bee-keepers of our State. Much of the discussion related to questions that have been discussed many times in conventions before, and which might seem to have been worn out; but we must not forget that much of our work is for the benefit of the younger and inexperienced, to whom these questions are important.

Some of the members of the Southwestern Wisconsin Association were with us, of whom N. E. France, the president of that society, was elected to an office in ours. Messrs. Van Allen and Williams, two enterprising young men from Boscobel, Wis., had on exhibition a six-frame automatic honey-extractor that seemed to please every one who examined it. The following is taken from brief notes of the sessions:

The convention was called to order by President Frank Wilcox, at 1:30 P.M., in a room of the State-house. The minutes of the last meeting were read and approved.

N. E. France, of Platteville, stated that he had been sent as a special delegate of the Southwestern Wisconsin Association, for the purpose of working with us for the passage of a foul-brood bill, and asked the privilege of having the question inserted in the program. Pres. Wilcox replied that it is proper to introduce any question by simply writing it on a slip of paper and handing it to the chairman.

Mr. Tawle called for the report of the committee appointed last year to present the request of the association for lower freight rates on extracted honey. H. Lathrop reported that the request had been presented in due form to the chairman of the Western Classification Committee, Mr. Ripley, who had promised to bring it before the meeting of the committee in November; but a list of tariff changes made in

that meeting, which had since been sent out, did not contain any reference to extracted honey.

A letter from the commission house of S. T. Fish & Co., Chicago, was read, in which they answered several questions on the program, as follows:

Glass fronts to shipping-cases should not be dispensed with. We would not allow any one to ship up comb honey unless it had glass fronts, and we think that any one who wants to change the present style of case is making a mistake. The railroad companies request that the glass be covered; but in every instance where this has been done, honey has arrived in bad order, as the freight-handlers are not aware of the contents of the cases; while if the cases have glass fronts it is handled with care.

They also spoke very decidedly against dispensing with the use of separators. They do not think statistics of the bee-keeping industry is of any benefit. They preferred extracted honey in barrels, half-barrels, and kegs, or in 60-lb. cans; but they could not pay any more for it when in cans.

Mr. Van Allen said it was of great benefit to the retailer to have glass fronts in shipping-crates. H. Lathrop described how he protected the fronts of single-tier crates by tacking a short piece of lath across each end, and then tacking a piece the full length of the crate on to these short pieces. This protected the glass, and conformed with the requirements of the railroad companies, and did not hide the contents of the crate. When the honey arrived in store these strips can be pulled off.

In regard to the use of separators the convention was about evenly divided for and against their use. It was generally considered safest for all, except the expert and careful bee-keeper, to use them. The question of supers was taken up, and on this there was also a division. Some declared they had the best success with deep wide frames, and others used the T super, or topless wide frame. It is evident that we have not yet found a surplus arrangement of such marked superiority that it will supersede all others.

It was voted to make the presidents of other bee-keepers' associations, attending our convention, honorary members. This admitted N. E. France, president of the Southwestern Wisconsin Bee-keepers' Association. At this juncture Mr. France announced that the next convention of their association would be held the first week in October, at the house of E. France, in Platteville, to which he invited all.

The question of foul-brood legislation was taken up. Mr. France spoke of the great danger to bee-keepers from foul brood, and read the draft of a proposed foul-brood bill, which was similar to the Canada law. A committee was appointed to present the bill to the legislature, and work for its passage.

The question, "Does it pay to feed back in order to finish partly filled sections?" was decided by vote in the negative; though some maintained it could be done with profit if properly managed. It was the general opinion of the members, that extracted honey should be thoroughly ripened, and on the hive was the proper place to do it.

Mr. Wilcox stated that, in melting up granulated honey, the water should not be allowed to get hotter than 140°, lest it should injure the delicate flavor of the honey.

MORNING SESSION, FEB. 7.

The first item of business was a resolution offered by Mr. Winter, extending the sympathy of the association to the bereaved family of our deceased brother, S. I. Freeborn, of Richland Center. The resolution was adopted, and a copy ordered to be sent to the family. It was the sickness and death of Mr. Freeborn that prevented the attendance of our former president, C. A. Hatch; if he had been present we expected something from him on the important question of brood-chamber capacity. The question was not discussed to any extent, and nothing new presented.

A letter from an absent member, Gustav Gross, of Milford, was read, in which he called attention to the fact that sweet clover was included in the list of noxious weeds. He thought we ought to do something to have the law changed. It was decided that, as we were asking for legislation on foul brood, it would not be best to do any thing about it now. In some places it would not do well, and in a few cases only the weed commissioners had condemned it. Mr. Hoffman said it was not a very good honey-plant in his location. Mr. France thought we had better sow alsike clover.

On the question, "What can we do to improve our association?" one suggested that each member bring one new one; another suggested that we get the ladies to attend. This was warmly seconded. Take notice, sisters, we expect you next year. Several members reported that their wives had intended to come along, but were prevented by sickness among the children at home.

The following were elected officers for the ensuing year:

President, Frank Wilcox, of Mauston; Recording Sec., H. Lathrop, Browntown; Corresponding Sec. and Treas., N. E. France, Platteville.

A paper sent in by W. H. Putnam, of River Falls, entitled, "Honey; how it should be Prepared for Market," was considered very good, and we therefore give it here in full.

Browntown, Wis., Mar. 5.

HONEY; HOW IT SHOULD BE PREPARED FOR MARKET.

I shall confine my remarks to the production and preparation of comb honey for the market. I do not wish or expect to impart much information to my fellow-members of this association, as most of

them, at least, are experts in this line. The great body of bee-keepers, however, are not members of this or any other association, and they are the people who need to improve in the preparation of their honey for the market. My ideal of a package of comb honey, if a 12-pound case, should weigh 11 pounds net; if a 24-pound case, it should weigh 22 lbs. net. The comb of each section should be confined within the wood of the section, so that, if a straight edge were drawn across its face, resting on the edge of the rim, it would not touch the comb. If honey is produced in this shape, each individual section can be removed from the shipping-case without disturbing the others. Precaution should also be taken against leaking. These are qualifications which the market demands, and the successful business man will cater to the trade.

People in other lines do put up their goods to suit the purchaser, and we must do the same if we would make money. For instance, a few years ago it became fashionable to color butter. The conservative people argued against it, and there was no end of clack and clamor against coloring butter. One of the most successful dairymen in my State (Wisconsin) favored the coloring of butter, because he said his customers demanded it; "and," he added, "if my customers send in an order for butter colored blue, the next shipment will be colored blue."

I make this digression to try to impress upon bee-keepers that the end of all our efforts is to make bee-keeping profitable; and if we would succeed we must cater to the trade. I had occasion recently to criticize a large producer of comb honey. That man raised nearly 4000 lbs. of comb honey in the poor year of 1894. I bought the whole amount at the price he asked, 10 cents a pound. I had difficulty in disposing of that honey because the crates were overweight, and the sections were not straight. You could not get one out without tearing the crate to pieces. When I had sold a customer one lot I could not sell him another. I criticized my friend, the producer, stating the reason why the trade wanted the scant sections, and got the following reply: "I do not care to put up honey for the dealer to beat the consumer on if I can help it." A long argument might be had on this point; but to cut it short, and state my view of the point, I will say, "Don't bite off your own nose to spite some one else;" dealers don't have to buy any man's honey unless it suits them, and it will suit them if they can make money on it. *Moral: Cater to the trade.*

Then I may briefly state my ideal crate of comb honey to have four necessary requisites:

1. It must be scant weight.
2. Combs must be straight.
3. They must not leak.
4. The 1-lb. is the standard.

How shall we obtain these requisites? If we would compete with Bro. Wilcox and Bro. France at the State fair next fall, we must lay the foundation now. If we would compete in the markets of the world we must make preparation at home long before the bees begin to swarm.

To accomplish these points we must adopt a section that, when filled full, will weigh about a pound. I consider the 4½x4½x1½ the proper size for general use with separators, and I do advise the use of separators by the general public. The members of this association do not need to use separators; they are skilled in their profession; they look to all the points; they keep their hives level; they keep their bees strong, so that, when they go into the surplus case, they fill it, and straight combs come naturally. For such bee-keepers I would advocate the 4½x4½x7 to the foot, and a full sheet of comb foundation. The average bee-keeper uses about 1 lb. of comb foundation for a bunch of 500 sections; his bees take care of themselves; some are strong, but most of them are weak; but a few bees go into the super at first; they cluster on some section; there is a vast unoccupied space all around them; honey is coming in slowly; they draw out the comb, and there is no limit to the size; it may bulge out on both sides, away past the edge of the section, and weigh 1½ to 2 pounds. Later, honey comes in more freely; more bees are hatching all the time, and after a while the case is filled. Later, when the bees more perfectly fill the case, some very straight combs may be found in the same case with some very bad ones. Had this person used separators he would have had all the combs straight, because the few bees would have occupied one or two sections somewhere in the center of the surplus case; where

they had drawn out the combs within about $\frac{3}{4}$ of an inch of the separator, they would have capped it over and gone on to the next section. In this way the honey of no section can protrude beyond the edge of the section, and we have gained our first two points. The combs are scant weight, and they are straight, and we have almost gained our third point; for, when the combs are straight, and do not bulge, there will be very little leaking. We can guard against all leaking if we will cut a piece of newspaper an inch larger than the bottom of our shipping-crate, and place it in the bottom, allowing the edge to turn up all around about $\frac{1}{4}$ to $\frac{1}{2}$ inch.

One more point about preventing honey from leaking. When honey is first stored in the combs it is thin and watery. It needs to be ripened. The water in it needs to be evaporated. Honey may be ripened on the hive; but if it is white it is better to remove it from the hive, because, if left on the hive, the bees will run over it, and the yellow pollen will fall off from their legs, and soil the combs, and the honey has to go for second quality, and be sold at from one to two cents a pound less. If, however, the honey is of a dark color, or is produced in a region where no buckwheat or goldenrod exists, it may be ripened on the hive. The reason why honey should be removed from the hive as soon as completed, if raised in a region where buckwheat exists, is that buckwheat honey, if dark-colored, and if only a few cells of dark honey are stored around the edge, even of the section, it places the whole in a second grade. When honey is removed from the hive, never place it *down cellar*; that is the worst thing you could do, because there is always more or less moisture in a cellar. If you place your honey down cellar, I will tell you what happens. The honey takes on moisture; and as two particles can not occupy the same space at the same time, the cells are expanded, the capping bursts, the contents of the cells become more watery, part of it oozes out, a chemical process takes place, and, the first you know, that honey is all over the floor. You taste of it, and it is sour. I presume what I have just related takes place in nine-tenths of the grocery stores in the country. Grocers are in the habit of keeping their molasses, vegetables, and other produce in the cellar, and naturally the honey goes down there also, and it is damaged more or less according to the length of time it has been subjected to this process of taking on moisture. The customer pays 20 to 25 cents for a comb of that *stuff* called honey; they take it home; they taste potatoes, onions, codfish, and every thing usually kept in a grocery cellar. That fine flavor that bee-keepers talk about is gone, they don't like honey any way. Then people talk about adulterated honey, and no wonder. What shall we do? Ripen our honey above ground, in some dry, clean, warm room where the air is pure, so that what surplus moisture there is will evaporate. If the weather is damp and rainy, use a stove to dry the air, then our honey will thicken and preserve its flavor. When you sell a box of honey, tell the party not to put the honey in the ice-box nor down cellar, but, rather, put it on the pantry-shelf. If your customer is a grocer, give him a few pointers in a friendly way.

And now I come to the fourth point. The one-pound is the standard. The pocketbook argument should have its effect here. First, if you use an odd size you must expect to pay the supply-dealer from 50 cents to \$.00 extra per 100, because it is more trouble to make odd size than regular sizes. Second, you must expect to get less for your honey. I will show you how much you would lose if you used a two-pound section. Suppose 2000 one-pound sections to cost at the factory \$5.00, you could not expect to get 1000 two-pound sections for less than \$4.00; and supposing 2000 lbs. of honey to sell at 14 cents a pound in one-pound sections, you could not expect it to sell for more than 13 cents in two-pound sections. In proof whereof I quote from the *Minneapolis Journal*, dated January 4, 1895.

Honey.—The market is slow, and prices are steady. Minnesota white clover, 14@15c; Wisconsin white clover, 14@15c; dark honey, 10@12c; extracted honey, 7c; 2-lb. comb, 15@14c.

Then we have saved \$1.00 on the cost of the sections, and we have lost \$20.00 on the honey; \$19.00 would be a big Christmas present; but it would be just like finding it, to a bee-keeper who was in the habit of using a 2-lb. section.

I wish to touch briefly upon how to secure the greatest amount of white honey. We hear so many bee-keepers say every year that they did not get any white honey, or very little white honey. The

plan generally pursued by the ordinary bee-keeper is to let his bees alone in the spring until they begin to swarm; then he hives the new swarm, and, after about two weeks, he puts on his surplus-cases. A little knowledge of honey-producing plants, and their time of blossoming, would change all this; for, be it understood once for all, bees do not make honey; they simply gather it, and store it in the hive. In my locality the first surplus honey comes from white clover, in May and June, followed by a short spell of no honey at all, and then comes the basswood the last of June and first of July. Basswood bloom is all over from July 10th to the 15th, and then comes another famine. In order to get white honey in my locality, the bee-keeper must have his bees in condition to gather honey by the middle of May. He must put on his surplus-cases as soon as his bees begin to build brace-combs. It is my practice to tier up as fast as possible, and sometimes I have two or three surplus-cases nearly filled at swarming time. As soon as a new swarm issues I remove the old hive a little to one side, placing it at right angles to the old stand. I place the new hive exactly where the old one stood; place the partly filled section-cases on the new hive; and in less than ten minutes after swarming, the cases are again filled with workers; each worker carries a sackful of honey with her when the swarm issues, and thirty or forty thousand bees can hold a considerable amount of honey. I have weighed new swarms that weigh eighteen to twenty pounds without the hive—in fact, before they had been put into the hive at all. I have no doubt that two-thirds of this weight was the honey in the bees. With me, bees swarm during white honey-flow; and by following the method here described, no time is lost; they go right on, and more cases may be added. Meantime the old hive is moved nearer and nearer the new hive, day by day, until they stand side by side and very close. On the seventh day after swarming, in the middle of the day when the most workers are in the field, quietly and carefully pick up the old hive; carry it quietly, and set it down softly at the greatest distance possible in the same yard, from its former position. Notice the effect. Almost instantly you will see a swarm, as it were, collecting around the place where this hive had stood; they are the workers returning from the field; their home is gone; they are confused, and fly aimlessly about for a few seconds; they alight at the entrance of the new hive; their mother is the queen there reigning; the bees have the same scent; they are received, deposit their load, and go again to the field for more honey. Likewise the workers that were in the old hive which we moved so carefully do not know their home has a new location; they go forth, but return to the old location; they are received, and a rousing swarm is the result. No wonder the honey-sections fill up quickly, as there are so many workers. But what happens at the old hive in its new location? Nearly all its working force has been drained away to the new swarm. In a day or two the new queen hatches. She has few bees to hamper her actions; she makes a tour of the hive, and murders her sleeping sister-queens, yet unborn. She is monarch of all she surveys, and there is none her right to dispute. You will not be troubled with second swarms. No time has been lost since white honey began to flow, and now we have the whole working force concentrated on comparatively few sections. If there is any white honey, we get it. After a week or two we can put sections on the old hive, and all our bees will be in shape for dark or fall honey.

River Falls, Wis.

DRONE-TRAPS, SELF-HIVERS, AND NON-SWARMERS.

DRONE AND QUEEN TRAPS MOST PRACTICABLE; "YOU PRESS THE BUTTON AND WE DO THE REST" HIVER WILL NEVER BE INVENTED.

By C. H. Dibbern.

A good deal has been said of late about how best to manage our apiaries in the bee-keeping of the future. It is generally admitted that,

for small apiaries of, say, less than 50 colonies, it will not pay to spend valuable time watching for swarms, especially in poor seasons; neither will it pay to let them go to the woods. In the large apiaries and out-yards the swarming season is usually a time of great anxiety and loss. Even if one has all his time free to look after the swarms, and every thing ready to do the hiving, it is usually hard hot work; and losses by doubling up and absconding are not always avoided.

Now, as the swarming season will soon be here again, the question is, no doubt, puzzling a good many—"How are we to control swarming?" Of all the many methods suggested of late years, the drone and queen trap method is, perhaps, the simplest and most satisfactory, so far as generally known. What is easier than putting the traps on the hives on the approach of the swarming season, and, when a swarm issues from one of them, simply putting an empty hive in its place, attaching the trap with the queen in it, and allowing the swarm to return when they please? There is no danger of the swarm absconding or doubling up with others as long as you trap all the queens. Should no one see the swarm it makes little difference, as the bee-keeper can easily determine any time, within two or three days, what hives have been swarming out, by finding a handful of bees with the queen in the trap, and fixing them up as desired. Surely this beats climbing trees, or running up and down the apiary with swarm-catchers, *a la* B. Taylor, all to pieces.

But why not carry this idea out further, and let the bees hive themselves? But how is this to be done? is the question I have studied for several years. Last year, and the one before, I described my devices that had proved partially successful; but the season developed serious defects. When the weather became hot, the strong colonies would crowd through the wood-zinc boards under the empty hives, and take possession and build comb there. This made it difficult to tell when a hive had actually swarmed, and it interfered too much with the work in the sections. Then, again, a hive would swarm; and when I supposed them nicely hived they would all go back through the board to their old home, except, perhaps, a handful or so, with the queen. To overcome these difficulties I substituted a solid board, except 4 inches of wire cloth at the rear end, to afford ventilation to the old hive, for the wood-zinc board. This worked all right; and when a swarm issued I would cut off the old entrance, and every bee would go into the new hive, where the queen was trapped, awaiting their return. When not present to cut off the direct entrance I would get only a part of the swarm; but I could always tell what hives had swarmed by looking in at the top, as the new hives are so cut off that the bees never take possession

without swarming. When I found these self-hived small swarms I had but to cut off the direct entrance to the old hive, to throw as many workers as wanted into the new one.

But now another difficulty appeared. When all the entrance was cut off, except through the bee-escape cones, from the old hive, the remaining bees would become alarmed, and commence in a day or two to destroy all their unsealed brood. This may be caused by their inability to get water, as bees never return when once through the escapes. I now leave an inch or so through the lower perforations, so that some bees can work from the old hive. At first I was a good deal puzzled to account for the small number of bees, and entire absence of brood in the old hive at the end of 10 or 12 days. I found invariably that, when cut off so that no bees could return, the unsealed brood would be destroyed. This, perhaps, explains the failure of such devices as the Langdon non-swarmers. I found that about 8 to 10 days was long enough to leave the old hive to boom the new, after hiving the swarm. If the surplus-cases are changed to the new hive at once, the work goes on with little interruption.

It has been urged against self-hivers, that the work and expense of preparing so many hives with foundation, in a large apiary, was too much work and bother. It is not necessary to prepare hives any faster than bees are ready to occupy them. As soon as I suspect there will be swarms soon, I put the queen-traps on all the strong colonies, and keep adding more as I have time. Now, as soon as a swarm issues from one of these hives I allow them to return once. This shows where an empty hive to receive the swarm is needed. I usually mark these hives, and fix them up during the day or evening, as I find time. When they again swarm out the next day or so, I simply place at the entrance a square stick, and fasten by a tack or two, to keep the bees from pushing it away, thus cutting off the old entrance, and compelling all the bees to go into the new hive. It seems to me it would be difficult to manage swarming more easily or more surely. Certainly it beats swarm-catchers, where one must be constantly on the watch, and generally on the jump, or cutting off limbs from valuable fruit-trees, and hanging them in holes dug in the ground "big as a barrel," to keep the swarms from doubling up.

I want to say, I do not claim that my device is entirely perfect, and I have no hivers for sale. Of course, in all such devices one must use a good deal of common sense. I do not believe that a "you press the bottom and we do the rest" hiver will ever be invented. The truth is, bees act very differently one season from another. I do know, however, that the idea is entirely practicable, and will soon come into general use.

Milan, Ill.

RAMBLE NO. 129.

AT NAPA; ON THE SACRAMENTO; JACK; GREASERS; WINERIES, ETC.

By Rambler.

HERE were a few partially civilized Americans living in Black Diamond, and these were allowed to come inside the "dead-line" around our camp. Mr.

Wilder had established such a line with our picket-ropes, to keep the horde of Dago kids from a too promiscuous mingling with our utensils. One of our American friends was pleased with our easy camp-chair, and, having apparently loaded up with beer, would come around and look at us as we worked at the picture business. It pleased him to tell us that he was electioneering for the office of justice of the peace, and had great hopes of election. He evidently thought that each jag of beer taken aboard was a harbinger of success. His heart was warmed toward us, and he gave us a sort of judicial opinion that our outfit was not complete without a dog; and as he had a surplus of that commodity on hand he would give us one. After seeing the embryo justice kick the dog with his heavy boot, and send him home limping, we decided to accept the gift. Jack was a splendid-looking specimen of the water spaniel, and his dam and granddam were traced back to Alaska. Jack adhered to the traditions of his forefathers, and was a good temperance dog, therein showing more sense than his master.

OFF FOR COLLINSVILLE.

We were to cross the river here. We had sought this place, for it was the cheapest one to cross. We were very busy until within an hour of boat time, and our spread-out camp had to be hustled into the wagon. Our would-be justice said we could not do it, and that we should have to wait two days for the next boat. But that man knew no more about hustling than a tadpole. He did not know of the conveniences of a collapsible camping-outfit, and we surprised him by driving to the wharf some minutes before the boat arrived.

The boat was one of the regular river craft

that ply between San Francisco and Sacramento, having a large undershot water-wheel in the rear. We just crossed the river to the town of Collinsville, not over five miles, and were on board less than an hour; and the ferriage, including the dog, was the modest sum of \$4.50. When we landed at Collinsville, and were hitching our ponies to the wagon, a fellow chipped another 25 cts. out of us for wharfage. We demurred greatly, and called it by its right name, a species of highway robbery. The explanation for this state of things is, that the rights and privileges of this waterway are controlled by the Southern Pacific Railroad. Their rule is to carry such an outfit as ours from San Francisco to Sacramento, over 100 miles, for \$4.50, or five miles for the same price, and we have to submit. "For ways that are dark, and tricks that are vain, the S. P. R. R. will beat the heathen Chinese."

We camped at Bird, four miles from the river; and the county we are now in bears the name of an Indian chief, Solano. A good portion of it rests upon Suisun Bay, and 100,000 acres of the county is tule swamp. These tule swamps are very fruitful all the year round, and the leading crop is mosquitoes. It is also a prolific breeding-place for frogs; and their hind quarters are temptingly displayed in the city markets. The next day, as we journeyed, a cloud of mosquitoes followed us. We were, fortunately, facing the coast breeze, and the cloud was left in the rear. Every conveyance we met, and that was going with the wind, had a fuzzy halo of the insects hovering over them.

Our observations in relation to bee culture were not rewarded with much success. Now and then a patch of wild sunflowers by the roadside would reveal various insects upon the flowers; but I saw only one honey-bee. Mr. Wilder saw another, showing that a colony was in the vicinity, bravely holding its own with the mosquitoes. Owing to the flat country, and its liability to inundation, the bee can not find lodgment in the ground; neither are there large

trees or rocky hills; so if the bees live here in the wild state it must be in the cornice of some residence; and even a house with such an appendage is somewhat rare after we leave the towns.

The lands above the river-bottom are devoted to the production of grain, and there is but scanty pasturage for bees. The tule lands are, however, in a fair way to be reclaimed. Great schemes are now on foot, so that, by a system of dykes and waterways, the rivers will be held in their natural beds, and the rich alluvial soil utilized for agricultural purposes. Then these low lands will become the natural home of al-

falfa; and wherever that is grown, we find the thriving bee-keeper; and I am not sure but some portions of Solano County already enjoy the benefits derived from the growth of alfalfa. The hoarse croak of the frog, and the high-keyed note of the mosquito, must give way to

"SANTA MARIA! DYNAMITO!"

the more industrious civilized hum of the honey-bee. It has been said, that the planting of eucalyptus-trees will banish mosquitos from a locality; but here we saw clouds of them while passing through avenues of gum-trees. Perhaps the avenues were not plentiful enough, or enough trees in the avenues. This being near the breeding-grounds of the insects it would probably require a tree to every square rod; and in case they were *Eucalyptus longifolia*, here would be another source of honey for the bees.

Whether it was mosquitos behind our horses, the untiring efforts of Jack to circle around our outfit, or our desire to get our mail, or a little of all three, we made a long drive that day; and in the early evening we dropped into the city of Napa. We were directed to a fine camping-place in the shade of some trees, and in that portion of the city known as Spanishtown. We were congratulating ourselves upon the shady situation, and had scarcely begun to erect our tent, when a woman with a very shady complexion, very large (I judge she weighed 300 lbs.), fat and greasy (you know these Spanish Mexicans are sometimes called greasers) appeared. Her first salutation was, "Why, what a pooty tent you have! Ble've I'll come and sleep in it to-night." Bro. Wilder dropped a tent-pin he was just going to drive, and I dropped a corner of the tent I was holding. Bro. Wilder recovered in a minute, and whacked away at the tent-pins again; and, not knowing what else to do, I took out my Water-

bury watch and commenced to wind, wind, wind. The shady fat woman had a look of curiosity at first; but wind, wind, wind; then a troubled expression of her swarthy features. Wind, wind, wind, and a step toward her, and she took alarm and shouted, "Santa Maria! dynamito!" and fled. No, she was too fat to flee; she got to her little cabin. She evidently thought I was fixing an infernal machine to throw at her.

We were soon after accosted by another Spanish woman, from another cabin. She was quite voluble of speech, and invited us to "beber vino" (drink wine) with her.

"No, señora," said I. "No necesitamos vino. Bebemos agua" (no, marm, we don't need wine; we drink water). We were thankful at last to be left in peaceful possession of our camp. We tied Jack in front of the tent, and, with my good Waterbury watch close at hand, we felt perfectly safe among the shady greasers.

We found in the morning, however, that these people were not all greasers. We could find no wood in the morning with which to prepare our breakfast. I entered one of the cabins to purchase a few sticks. The head of the house said I could have some; and after selecting four or five billets I asked him how much.

"DON'T YOU KNOW I AM A MISSOURIAN?"

"Oh! go along," said he. "We are Missourians; and don't yer know that, wherever you find a Missourian's home, you must walk right into the house and help yourself?"

I pocketed my dime I thought to give him, and paid him in thanks, which seemed to be satisfactory.

Napa is the great center of the wine industry of California. Vineyards and wineries are upon every hand. The viticultural associations and many good people, including some very prominent ladies, recommend the use of wine as a beverage, or as an appetizer at each meal. Owing to a delay in the arrival of our mail and express packages we were obliged to stop over here one day, and we had an opportunity to witness how delightfully the wine-bibbing practice worked.

Several of our Spanish neighbors, of both genders, and including our fat and our voluble acquaintances of the previous evening, gathered under the trees a few rods from us, around a demijohn of wine. It rapidly circled from person to person, until it was emptied; and after a short season it was sent to some convenient saloon and filléd. It then circled again. Result, a young Spaniard slipped from his chair and sought a slumberous attitude on the ground. A blanket was spread, and he was rolled upon it by the fat woman. If he as much as opened an eye, the dames were on hand to offer him more wine. Others of the group staggered off to some more private place to have a lethargic sleep. The señoras wound up their afternoon with what might be termed a jamboree of angry words. As the cool of the evening came, there came also two men and carried, rather than led, the limp form, that was still on the blanket, into one of the cabins. Thus the picture of the afternoon vanished.

Shall we take a little wine for the stomach's sake? Thus far on our journey Mr. Wilder and myself had not patronized the drink-shops, and this temperance lecture before us gave us an opportunity to renew our allegiance to cold water.

I have no sympathy with viticultural associations, for the scene among these poor Spaniards is daily reproduced in higher walks of life, and where the public eye can not behold the lethargic sleep or the domestic brawl. Therefore, still in the ranks of temperance reform will be found the Rambler.

JAKE SMITH'S LETTER.

FIVE-BANDED OR LONG-TONGUED BEES.

Mr. A. I. Gleanings—*dear Sir*:—Our Zed's always a fussin' at something. Last summer he got a lot of oyster-cans and put them on the different hives, with a little bit of feed in them. I didn't mind it, for it was a bad season and the bees wan't a gettin' nothin'; and I didn't care if he did feed em sunthin'. Zed's a good boy, if I do say it, and when he hain't into no mischief I let him have his own fun.

One day Jim Short he come over, and we was

a talkin' about how the corn was a dryin' up without fillin', when Jim see Zed a fussin' at the hives.

"What's Zed up to now?" says he. "He ain't a takin' off honey, is he?"

"Oh, no," says I; "the bees ain't a makin' any honey now. It's a bad year for bees as well as every thing else. I guess Zed's a tryin' to get the bees to hatch out a crop of oysters."

I jist said it for fun, for I knowed he was a feedin' em. And I told him so.

Then he went over toward where Zed was, and says Jim to Zed, "You'll get your bees trained so they'll be no good."

"How's that?" says Zed.

"Why, they'll git used to lookin' to you for feed, and then when any honey does come in the blooms they won't go after it."

"I guess all I give 'em won't spoil 'em very bad," says Zed. "Come and see how much I give 'em."

"Jimminy!" says Jim. "Why, they hain't no feed there at all."

"Yes, there is too," says Zed. "You see, there's a false bottom there. And you see all those little holes in it for the bees to reach their tongues through. Well, there's just a little feed on the true bottom. And the true bottom's on a little slant, so you can tell just how far the bees' tongues reach. They'll suck up the feed just as long as they can; and when it's out of their reach, of course they'll have to stop."

"Oh! I see," says Jim; "you make 'em reach as long as they can, and then they'll stretch their tongues a little farther, and that way you'll grow a long-tongued set of bees."

"Say-ee!" says Zed, "why wouldn't that work?"

"I guess," says I, "you'd have to have a good many stretches to make much difference, and the whole hive would have to be at it all summer long, and may be a hundred summers for any thing I know."

"I guess that's so," says Zed, a fetchin' a long breath. "But that wasn't what I was after, though it ain't so far from it either. You see, bees' tongues ain't all of a length, not by a long shot. Now you see that feed comes up to the seventh hole. Now let's go to this next hive. Two, four, five—this comes only to the fifth hole. You see there's a good bit of difference in the tongues of these two colonies, and it's that way all over the yard. Some of 'em must have tongues a half longer than others. I guess I better get this cover on, for the robbers are gettin' around."

"Well, now," says I, "what good will it do if you take the measure of every bee? It won't make 'em any longer or shorter. If you could make 'em longer you might git 'em to work on red clover. But you can't do it."

"Don't be too sure of that," says Zed. "You can do what amounts to the same thing. Suppose you measure tongues in every hive. Then

breed from the long-tongued chaps, and weed out all the short ones. You know there's been red-clover queens one time and another wrote about. But I guess they all run out in a little while. My notion is, that those red-clover bees had extra long tongues; but the only way to tell it was to see the difference in their yield, and you couldn't keep that up so to rely on it. Now, if you had a red-clover queen to breed from, or, what's the same thing, breed from your longest-tongued bees, and raise drones from the same, don't you see you could tell what you was a doin'? And you could keep that up."

"It wouldn't be no use where there's no red clover," says Jim.

"I believe it would," says Zed. "You know you'll have two hives just alike every way, fur as you can see, and one will store ever so much more than the other, and nobody can tell why. It's the difference in their tongues, along with the difference in flowers. Red-clover honey's too deep to reach. Now, it stands to reason that other flowers may be as deep or deeper than red clover; and even on white clover the bees with the shortest tongues might have hard work to reach all the honey in the blossom."

I thought to myself that wasn't sech a bad idee, but I didn't say it.

Zed went on, and, says he, "When they're tryin' to make out which is the best race, and whether five bands or three bands is best, let them settle it by measurin' of their tongues."

"Yes," says Jim, "first thing you know they'll have a fair, and bees from all over will be sent in to get the prize for the longest tongues. Then they'll quit advertisin' 5, 10, or 15 bands; but the advertisements will read, 'Queens for sale warrant to raise bees with tongues three-quarters of an inch long.'"

OPERATING A BEE-ESCAPE.

THE PORTER AND ITS PRINCIPLE RECONSIDERED

By C. W. Dayton.

I consider that the statement (in *Review* and *Gleanings*), that I was using Porter escapes both in experiment and actual practice, was a fair acknowledgment; but the final report upon them I shall not be prepared to make for a season or two yet. The past season I used four different kinds of escapes in removing 6000 lbs. of comb and extracted honey. Also several colonies were kept busy going through escapes from May to October, and it has become my opinion that the Porter, or, for that matter, the Stampede, is only a "stepping-stone" to an escape which is far better than either.

That escapes are an advantage is no question with me; for, during the past season, I kept an apiary within 54 feet of a much traveled highway. To open a hive and brush bees from

the combs of but one hive sent angry bees thickly after passing teams and people. Escapes, on the other hand, prevented a single molestation. To keep bees and take honey where I was located, without escapes, was positively out of the question. Where bees were once looked upon as a terror, there became a friendly disposition toward them.

When I began to experiment it was found that the bees of some colonies went out much more readily than others. The stampeding disposition was discovered, and some of the forms of escapes sent were far more favorable to stampeding bees than others. Prior to this I had used Porter escapes, but did not inquire into the philosophy of their operation any more than to put them on and remove the supers when empty. But when two escapes, which were exactly alike, were placed upon two colonies apparently alike, and the operation considerably different, it was queried where the differing existed—in the escape or in the disposition of the bees, or what?

The average time taken was perhaps twelve hours; but sometimes the time would be shortened down to three hours. I began to inquire into the reason for having the channel of the single-exit Porter of double-bee-space depth. Then after a bee gets down into the channel, and is about to proceed toward the springs, it must ascend an elevation in the floor. Under this elevation is an opening as if prepared for the deception of bees which were seeking a route to get back into the super. At the side of the elevated portion of the floor are two spaces as if for the passage of air. This elevation in the floor is a hindrance to stampeding bees. Then the round entrance to the channel is widely flanged downward, so as to interfere with stampeding bees passing forward. As a rule, the first bees to try the springs seldom go through until they return and inspect every other part of the escape or escape-board. I don't believe they want to go through the springs. But the depth of the rear part of the channel, and the flanged aperture, prevents their getting back into the super again, and they are finally forced to go through the springs, from thinking there is no other exit; thus when the bees get down into the channel they are in a trap. Observation teaches that, when the main force of bees get started they crowd through without attempting to turn about toward the super. Now, the number of bees which are liable to be trapped by this double depth of channel and flanged entrance to the same does not amount to 50 bees per super, which bees, if joining the throng, would go through in a few seconds. But these arrangements tend to defeat the purpose of the escape by retarding the main tumult. These first bees to test the springs are of a meddlesome disposition, and do not know that they are separated from the queen; and to construct imple-

ments to trap them is impractical. After a while a few of the clustered bees come down on the escape-board. They are not meddlesome, nor will they fight. These are the bees to set up a line of fanners, as soon as they discover the route to the brood-chamber, which rapidly augments in numbers.

Many times I have held the Porter escapes in my hands and wished they (Porters) had only done enough "ax-grinding" to explain the disposition of the bees toward every part of the implement. I would furnish the "stone" gladly. It was the failure in them to do this which caused me to do so much experimenting and philosophizing, and I produced the Stampede to illustrate the necessity of a wider exit; the going-toward-the-light, and other principles. I believe that the going-toward-the-light is one of the best principles in an escape, if we find out how to apply it. If we do not know how to apply it, it may be the worst. I do not think it can be employed in the Stampede or Porter as conveniently as in an escape that is sure to arrive within one or two years hence. I believe the perfect escape will possess a trap, but not a channel. When the bees progress a distance in a horizontal direction, turn an angle, and proceed onward to reach the brood-chamber, energy is wasted, the same as draft is wasted by an elbow in the pipe to the stove. I do not think escapes can be compared accurately by adjusting several in a board. It is the operation of the bees more than of the escapes.

I challenge any one to produce one line of theory from my articles which can not be demonstrated as actual fact, beyond a reasonable doubt.

Florence, Cal.

[Yes, I hope our inventors will not be too backward on this "ax-grinding" act. If they go too far I'll try to shut 'em off.—ED.]

THE PART THAT LOCALITY PLAYS IN DECIDING UPON THE BEST SITE FOR THE BROOD-CHAMBER.

By J. E. Crane.

It is not often that I "take my pen in hand" to write to any of the bee-journals; so that, while I miss saying a good many things I should like to say, I am at least left to judge more disinterestedly in regard to what others write, because I have not committed myself to many of the views advanced.

As I look back over the years, there seems to be something of fashion in bee-keeping as in other things. Only a few years ago, revolving hives and frames were the fashion, though we hear but little of them now. Farther back, large brood-chambers were strongly advocated; and, later, smaller ones have been considered best; and now, again, like the sleeves of a fashionably dressed woman, the tendency is to enlargement. Meanwhile Dr. Miller sits serenely

on the fence, the most sensible man in the crowd.

I do not now remember any good reason for the adoption of a large brood-chamber, unless it has been that bees do better in them. And so small hives were adopted because they were thought to be more profitable than large ones. It has surprised me that so little *proof*, by actual experiment, has been offered. Surely here is a nut for the "Experiment Station" to crack. And yet I doubt whether, if it were conclusively proved that large hives were better than small ones in a given apiary, it would follow that they would be better in some other apiary five miles away. Here in my home apiary I use, mostly, hives with seven or eight Langstroth frames. Some years ago I brought in six or seven hives with large brood-chambers—ten or more combs. As the combs were crooked and irregular I let them remain for several years as they were unless it was to remove the surplus drone comb and substitute worker comb instead. And now I think I can say that I received twice the profit, on an average, from my colonies in small brood-chambers that I did from those in large brood-chambers.

More than this, within a few years a neighbor has put out an apiary near me. He worked for me two seasons, and knew very well how to care for bees before that; but he has kept his own stock in large brood-chambers, while I have kept mine in small. I told him recently that I thought he had not received one-half the profit to the hive that I had, and he was quite ready to agree with me.

Now, does not all this prove quite conclusively that a small brood-chamber is better than a large one? It certainly looks so. But, hold on a little. I have several out-apiaries. One of them, six miles away, I have for several years kept mostly on seven or eight Langstroth frames. Close by it my brother's wife has a small apiary in large brood-chambers, with ten or eleven Langstroth combs to the hive. She does not believe in feeding—says that, if bees can not get their own living, they may die. So she did not feed at all the past season, while I had to feed quite heavily both spring and fall, and her yard averaged more marketable surplus honey to the hive than mine, and I think twice the profit with one-half the care. Hurrah for the large brood-chamber!

Now, here is experiment and positive proof to my mind that both are best and that neither is best. But what makes the difference? What are the principles that underlie the subject that make a large or small brood-chamber more valuable in a given location than the other size? All were wintered alike out of doors, all were on the same size of frame; and, so far as I know, the bees were equally good workers.

I believe we have not far to look for an answer. In my home yard the bees have an al-

most continuous flow of honey from willows and maples, from flower-gardens, fruit-trees, and dandelions, from early April until June, and brood-rearing progresses with great rapidity. The brood-chamber being small, the brood can be kept warm with fewer bees, and more workers are sent to the fields; and, the faster the honey comes in, the faster the brood is spread, and strong colonies early in the season is the result.

How is it in the yard six miles away? The conditions are quite different. Very little early honey is to be had; and, while the small brood-chamber always contains ample honey for present needs (for we feed if they do not), the bees will not spread their brood as fast as where there are from 15 to 20 lbs. or more of old honey at the sides of their hives.

Again, I have found hives with a large brood-chamber and "lots" of honey, rearing brood later in the season than hives with less room and less honey, and so go through the winter stronger.

Again, it is necessary to feed colonies in a small brood-chamber much more in autumn to winter them than is necessary to feed to those in a large brood-chamber; and it now seems very doubtful whether sugar syrup is as good to stimulate brood-rearing as is pure honey.

So it comes to pass that, where but little honey is gathered in early spring, the large brood-chamber has the advantage of a small one. But suppose we feed the colony in the small hive very heavily in autumn, will not that help the matter? My experience has been that, where a small brood-chamber is crowded with bees and honey, the bees will rear a large amount of brood in winter, and the vitality of the bees and their stores both be exhausted.

I formerly reasoned in this way: What is the use of letting a colony of bees occupy eleven frames when eight are all they really need for brood and a moderate supply of honey? Why not have the eighteen pounds of honey that it would take to fill those extra combs, stored in boxes which would sell for \$2.00 above the cost of sections, etc., and then in the fall feed 15 lbs. of sugar, which would cost less than a dollar, and thus make a dollar clear to each hive, which, on 500 hives, would be no small sum? The logic seems to be all right; but in practice I have only one yard where it is an entire success, and that is where the bees get an abundance of early honey, and here a small brood-chamber is much more profitable than a large one. In our other yard it would seem to be about an even thing, and in all my other yards the large brood-chamber has decidedly the advantage, unless in exceptional seasons when there happens to be an unusual yield of early honey.

Middlebury, Vt., Jan. 19.

—*Bee-keepers' Review* for February.

INCREASING COLONIES.

Question.—Owing to the past cold winter, bees are coming out very poorly this spring, some having lost from one-third to two-thirds of their colonies, and others nearly all they had last fall. Now, what we wish to know is, how to build up the colonies we have left, so that the combs can be occupied, and our apiaries be prosperous again. We elect you as our general; so, go ahead that we may follow.

Answer.—I am very sorry to hear of the many losses, from reports which are coming in, but am glad to see the cheerful spirit manifested in going about building up again, and will gladly do all I can to help. In this building-up process, all want one or more boxes similar to a honey-case, only having wire-cloth sides, and a hole in the top which will admit a funnel, such as is used in putting up bees by the pound, this hole having something like a door to easily close it with; and one of the wire-cloth sides should be tacked to small wooden strips, and thus made easily removable. All how to make these "nuclei boxes" has been given by myself in back volumes of GLEANINGS. As early in the spring as you can do so without loss by cold spells, begin to stimulate the very strongest colonies you have, by spreading the brood and feeding (being sure that you do not go too fast), so that these colonies may swarm early, thus giving you queen-cells, or build queen-cells for you by the plan given in my book, so that you can have plenty of queen-cells to use as you wish them, if you prefer to raise your queens to purchasing them. Having the queen-cells nearly mature, or having queens on hand by purchase or otherwise, go to the colonies which can spare bees without damaging their building-up as fast as you desire, and take out two frames having to the amount of about one-half pound of bees on them, being sure the old queen is not on these combs. Set them down on the outside of the hive, and tap gently on them so as to cause the bees to fill themselves with honey; and as soon as they are filled shake them down through the funnel into the box, removing the funnel and closing the hole. While the bees are filling themselves with honey, you can go to other colonies and take out frames of bees from them, and thus keep things moving right along, instead of waiting as you will have to if there is only one colony in the apiary.

Having the bees in the box, return the combs of brood to their old place in the hive, marking the one having the most hatching brood, so you can get it in a moment when wanted. Now set the boxes of bees in a cool dark place,

and leave them till near night—just time enough so you can finish your work before it becomes so dark you can not see. At the right time, go to the hive from which you took the bees, and get the marked comb, shaking the bees which are on it in front of the entrance, and put a frame of comb from which the bees have died, in its place. Now take your comb of brood and a frame of honey, left from your dead colonies, and place them in a hive where you wish a colony to stand, putting in a division-board so as to make a small hive for the two combs. Go to your hive having queen-cells, and take one of them, fitting it into the comb having the brood, at the upper edge of said brood. Now close the entrance to the hive; get the box of bees, and put it with the funnel-hole next the combs; open the door over this hole; and if the box is within three-eighths of an inch of the brood, the bees will immediately run out of the box on the combs. As soon as they begin to run out, close the hive, and the work is done till next morning, when you will take out the box, adjust the division-board, and open the entrance. As soon as the young queen from the cell given gets to laying, you are ready to insert your combs from the dead colonies till the hive is filled, giving the combs as fast as the bees can occupy them. In the above, I have given the mode of making one little colony; and you are to make as many and as often as you have colonies that can spare bees and queen-cells to give the bees, using about half a pound of bees for each colony made during June, one pound during July, and two pounds during August. Where we have plenty of combs to use, there should be no trouble in making ten colonies from one old one in the spring, as I have repeatedly proven. If you prefer to purchase queens, instead of raising them, then you will proceed the same as above given; but instead of doing any thing about putting the bees in the hive at night, you will place the queen in a provisioned cage, go to your box of bees, and, by setting the box down suddenly, drop them all to the bottom, when the caged queen is to be hung in so the top of the cage touches the top of the box, and the bees left till the next morning, when the hive is to be fixed as before, less the queen-cell; and, instead of opening the funnel-hole for the bees to run out of it, the movable side is taken off, and the bees hived like a swarm, letting the queen out of the cage so she can go in with them. Or if you do not prefer this plan at all, then let the colonies swarm as fast as they will; and, six days after any swarm issued, divide the old colony into nuclei, using two combs with bees, brood, and a queen-cell to start a separate colony, and build up these nuclei with the combs not occupied with bees. In this way you can make six good colonies from one in the spring, and often secure quite a surplus from the new swarm.

DIVIDING COLONIES.

Question.—I wish to divide each of my colonies just once; thereby securing the increase I desire. How would you proceed to do this if you had virgin or laying queens to give the queenless half?

Answer.—Having the queens on hand, as it is supposed in the above question, go to any colony preparing to swarm, or one that has its hive full of bees and brood, and move it to one side of the old location, so as to put a new hive in its place. If a hive is not full of brood and bees, do not touch it; for it is useless to try to increase bees till such is the case. Now look over the combs until you find the one having the queen on it, when you will place said comb in the new hive. Next give them a frame having some honey in it, and then fill out the hive with empty combs or foundation, when about two-thirds of the bees in the old hive are to be shaken in front of the new hive, and allowed to run in. Now arrange the frames back in the old hive, putting a division-board in place of the frames taken out, when the old hive is to be carried to a new location where it is wished that it should remain. After the bees thus removed have become reconciled to their queenless condition, or in from 24 to 36 hours, give them a virgin or laying queen in a cage, in the mouth of which is enough Good candy so that it will take them from three to four hours to eat it out, thus liberating the queen. When the queen gets to laying, take out the division-board and fill out the hive with combs or foundation. In this way we secure a new swarm, control all after-swarming, and introduce a young queen, all to our liking and with but little trouble.

HONEY-CAKE RECIPE.

As I know a good recipe to make honey-cake, I will publish it for the benefit of others: Five eggs; 2 cups honey; 1 cup sugar; cinnamon; one teaspoonful soda. Beat the eggs with sugar; heat the honey lightly; stir in soda with one spoonful of warm water, then pour it all together. Stir as much flour to it, to roll out for cakes. When eggs are scarce I take two eggs or none, but a cup of lard, two cups honey, one of sugar, etc. I prefer this recipe. I make cakes, or pour it in a pan. It never fails to be good in either shape. Just try it. You and the children will be satisfied. We eat honey three times a day, the whole year round. Guajilla and catsclaw honey have a fine taste. The more you eat, the better you like it.

MRS. ANNIE SCHUDDMAGEN.

Sabinal, Texas.

NO SELF-SPACING DEVICE WANTED.

The 100 thick-top frames I ordered of you, and received Aug. 30, 1894, I think are the best made; in fact, I would not give them for any other. I like a plain frame. I do not like the Hoffman, or a frame with a tack driven in the edge to space them. I always fix the space on the hive, and not make the frames self-spacing; by doing this there is no need of having any other than a plain thick-top frame.

S. F. SAMPSON.

Ronceverte, W. Va., Feb. 11.

[All the manufacturers, I believe, allow their customers the option of self-spacing or non-spacing frames, for it is impossible to please every one with one style of frame.—ED.]

ROBBERS, AND CRACKS AND CREVICES.

I want to say something to you, where you are giving advice about robbing. You say, on p. 251, in the A B C, "Close all cracks and crevices." Now, I want to ask right here, what will start robbing quicker than to have such cracks and crevices in a hive? I want to say again, that, if bee-keepers can't make or furnish hives for their bees, that have not such cracks in, they ought not to keep bees at all.

Big Rapids, Mich.

A. A. JOLDS.

[The item to which you refer was written before the advent of the present modern factory-made hives, with their nice-fitting joints, and referred more particularly to the bee-keeper who made them himself. I agree with you, that there should be no cracks or crevices in a well-regulated apiary; for surely in this case prevention is better than cure.—ED.]

FIVE-BANDED STOCK; DIFFICULTY OF BREEDING THEM TRUE TO MARKINGS.

I ordered, about three years ago, a five-banded queen and two untested queens from a pure five-banded mother. The queens reared from the five-banded queen, in every instance so far as I know, produced queens that, in every respect, resembled the mother—finely marked, and, in the majority of instances, the daughters produced a full three-banded stock, while the other two untested queens, from the five-banded mother, or claimed to be, produced as fine, distinct, three-banded bees as I ever saw; but neither of them was fit to rear queens from. The daughters from them were a motley set, and, in the majority of instances, would produce hybrids, from black all the way to four bands. Some of the daughters from these queens would be black, while others would be yellow to the tip. I keep no black bees in my apiary, and there are but very few in the vicinity—none less than two and three miles. That was my first experience with these bees.

I made a further experiment, however, and found about the same. I ordered, in August, 1892, three untested queens from a pure five-banded mother. This, as in the other instance, I believe to have been from a perfectly reliable breeder. They were all safely introduced, and proved to produce strictly three-banded prog-

eny, but many running as high as four bands—none less than three. I bred from these queens, and found one to reproduce the markings of the mother; but the other two did not reproduce their markings in their daughters. Some of their daughters were not more fit to breed from than a hybrid mother; and I will state right here that no queen that will not reproduce herself in her daughters is fit to breed from. So I came to the conclusion that the first cross on these queens, even if by a black drone, the progeny would be a respectable three-banded bee; but to breed further would be a cross hybrid of the most vindictive nature. My experience proves to me, at least, that all bright queens will not do as breeders; for, while black blood may not show on the first cross, it will crop out in the continuation of breeding, if there ever was the least particle in the mother.

Coronaca, S. C., Feb. 13.

J. D. FOOSHE.

HOW TO PROTECT AN APIARY FROM THIEVES;

A SILENT NIGHT-WATCH THAT BOARDS ITSELF AND WORKS FOR NOTHING.

I have been troubled with thieves in my apiary this season robbing one colony of fine Italians of all the honey, with frames, right after the fall flow, thus destroying the colony entirely. Now, what I should like to know is this: Can I procure some powder cartridges, similar to the 5 or 10c. caution firecracker, sold for 4th of July celebration for the small boy, that will explode by pulling it apart, or, in other words, by friction, instead of a spark of fire? My idea is, to have one of these fitted to a hive using an outer case, and so adjusted that, when the cover or top is removed, it will explode the cartridge, causing a loud report, thus not only frightening the thief, but also giving the alarm to the apiarist. I intend to fix up something that will do the business, even with shells used in a shot-gun, $3\frac{1}{2}$ drams of powder, and heavy wads; but I think cartridges designed for this special purpose, making a loud report, would be much better if they could be procured, which could be exploded by friction of the parts.

JOHN K. GOODRICH.

Waterbury, Conn., Nov. 25.

[It would be rather expensive. I think, to get up a special cartridge that could be attached to hives; and even then, if it worked as planned, it would scare away the thief instead of aiding in his capture. A far better and cheaper arrangement, and one that we once used around a poultry-yard to keep away thieves, is a simple electric bell, small battery, and a spool of linen thread. We simply stretched the thread around where the chickens were housed in small coops. It was black, and was passed through small screw eyes attached to trees. Of course, in the night time this would be invisible, especially if only about two feet from the ground. This thread should run clear around the apiary or poultry-yard. One end should be made fast, and the other tied to a wooden plug slipped between two brass clips, representing the poles of the battery. The battery wire and bell may reach to the house and into the bedroom. The

minute an intruder runs against the linen thread it will draw the wooden plug out and allow the spring clips to come together and complete the circuit of the battery, when the bell will ring in the bedroom and give the alarm, unknown to the thief. In our own case, fortunately or unfortunately, the thief did not come any more. If he had he would have been surprised. Now, this plan will protect 100 colonies at a cost not to exceed \$1.50 for material, and perhaps three or four hours' time in putting up.—Ed.]

THE HEDDON DIVISIBLE-BROOD-CHAMBER HIVE;
THE DANZENBAKER HIVE, AND THE
QUESTION OF INFRINGEMENT.

When Mr. Heddon saw the article by Mr. Danzenbaker, which we published on page 221, he requested the privilege of replying to the same, saying his reply would be fair, courteous, and logical. As Rambler and one or two others had expressed themselves privately as of the opinion that the D. hive was a direct infringement on the Heddon patent, if any thing was, it seemed no more than fair to Mr. Heddon that the request be granted. It is important, I think, that the question of infringement, if any, and just what Mr. Heddon's patent does cover, be discussed fairly and candidly—more so than for the parties to resort to the process of law. The reply is as follows:

THE DANZENBAKER (?) HIVE.

Bro. Root:—I have just read Mr. Danzenbaker's article and your editorial comments regarding the same. On this, above all other subjects, do beekeepers need information. I am very glad to note your sincere and intelligent views regarding our national laws giving adequate titles to the earners of property. First, I will say that I am surprised at your statement that you have not received the *Quarterly* edition of my paper, devoted to bee culture. It was mailed you promptly, over six weeks ago; but we know mistakes will occur in our offices and on our railroads. But now allow me space to make clear to your readers the relation between Mr. Danzenbaker and myself.

Bro. John H. Martin (Rambler), of California, has sent a communication to me which will appear in my April issue. In that communication occurs the following:

Recently in my travels in this State I have found a great variety in the size of brood-frames, and the tendency seems to be toward the shallow frame. Mr. Brodbeck, of Los Angeles, reduces the depth of the Hoffman an inch or more. Mr. Flory, in Central California, uses a similar frame. These straws show the tendency of the times; and the shallower the hive used, the more pronounced becomes the liability of infringement. Mr. Heddon says that, when straws become sawlogs, there is some meaning to them. Here comes the sawlog. When in Los Angeles a few days since, attending our State convention, my attention was called to a divisible-brood-chamber hive, invented and patented by Mr. F. Danzenbaker, of Washington, D. C. I do not know what Mr. Danzenbaker's claims are; but this

I do know, that, at first glance, any person at all familiar with the Heddon hive, would say at once, "Why, there is a Heddon hive." A closer examination reveals the fact that the thumb-screws are missing; and the case, instead of having eight frames, contains ten, and there is a sheet metal lining in the ends which also serves for supporting the frames, which are a duplicate of the Heddon. In making his frame close fitting together, and also to the case, the combination is clearly an infringement upon the Heddon claim.

The sheet-metal lining and rest, or frame-support, used by Mr. Danzenbaker, we consider very objectionable, expensive, and a failing effort to overcome supposed weaknesses that do not exist in our hive.

That sheet metal will not hold the frame tightly together, nor tightly to the case, for shaking and inverting; and if it would, it would be an infringement upon that special function of my invention, in the use of close-fitting frames, at the same time closely fitting the ends of the case. Whether Mr. Danzenbaker's features are better or worse, they can not be made, used, or sold, without laying all parties liable for infringement. My circular quotes patent laws, giving all the reasons why. The only damage Mr. Danzenbaker's hive can do is to lead bee-keepers into infringements, and away from better devices.

Mr. Martin says that a brood-chamber, made in divisible parts, and used as specified in our patent, is well adapted to California, and we are sure he is correct; for it is equally adapted to any spot on earth. While it was constructed principally for safety and time-saving in manipulating the apiary, it has been repeatedly demonstrated, since we brought out the hive, that a divisible or multiple brood-chamber winters bees more safely, and that they breed up faster in the shallow tiers of frame, than in any other style of hive. Hundreds have so testified; but, as stated before, to fully carry out safety and economy in manipulation, the frames must be fixed, and our manner of adjusting them tightly to each other at their ends, by the use of set-screws, and sufficiently close to the ends of the case that they are readily movable, yet the bees can not go behind them, is the only one we believe to be possible, so long as bees keep their present instincts. The set-screws are the only device which will securely hold the frames, for the needed manipulations in carrying out to completion the new system of management. Mr. Martin is acquainted with the state of the art, consequently he knows what is my property, and in his article makes that knowledge known to our readers. It must be his inquiry relates to the question as to whether there may not be a flaw in the title upon which I depend for the protection of my property. I am quite certain there is not, Bro. Martin; but if there were, do you understand that bee-keepers would rob me of what they know to be the results of my labor, provided the sheriff was absent? Laws are not virtues, but necessary evils; necessary to protect virtue and industry from crime and idleness. Law doesn't make right and wrong, *per se*. You know of what my invention consists, and you know it is my property, whether I had any patent-deed to it or not. But I have, as you know; and allow me to add that it is a good strong one, for, as the great authority, Walker, states, "The state of the art to which an invention belongs, at the time that invention was made, must be considered in construing any claim for that invention."

Since Langstroth was robbed, a patent court of equity has been established. This was done in 1870.

The establishment of that court enables you, my rambling brother bee-keeper, to make a much better guess as to how I shall come out when I am compelled to defend my natural rights in United States courts than could a judge on the United States supreme bench, who was not acquainted with the state of the art to which my invention belongs. The patent court of equity gives unto Cæsar the things which are Cæsar's. We have no dispute about the ownership of what the state of our art shows through its literature and otherwise, as was brought forward by me.

The divisible brood-chamber, with its collateral functions, was constructed especially to carry out a new system of management, neither one of which was known before the issuance of my patent. I have none, nor could I have a patent on any particular depth, length, or capacity of a frame or brood-chamber. My patent covers a divisible brood-chamber, *used as and for the purposes specified in said patent*. These purposes specified are the same as have been time and again written in bee-journals, my circulars, and book. There is no mistaking it, and no getting around it. In Langstroth's time, a popular method of deceiving the public was to procure a hive-patent on some minor or inconsequential feature which the claims covered, while the specifications (of which the drawings form a part) *showed* the essential features of father Langstroth's valuable patented invention. The uneducated public supposed it had a right to use the "patented hives," just as illustrated in the Jones, Smith, or Brown patents; but no such thing is true. They procured the right to use only what was *claimed* in the claims in these worthless patents, the patent office presupposing that Jones, Smith, and Brown would purchase of Mr. Langstroth the right to use his invention before they would use or sell their own. It is as though I had invented a bundle-carrier for a McCormick reaper. Before my invention is available, I must procure a right of Mr. McCormick, or sell my invention to him for what I can get for it. A patented machine or manufacture may infringe some other patent just as much as one that is not patented; remember that. Also, please remember that a patent is not property, but an attempt to give a title to property.

One writer has asked me why I don't begin prosecution against Mr. Danzenbaker. Why should I make haste? In most cases it is much cheaper and better for me to begin suit against his customers; but why make haste? Every one infringing my patent is liable, and the law gives me six years after the expiration of my patent, or until 1908, to collect royalty from all who infringe. There is no hurry; nearly all bee-keepers are fairly well informed, and it is rarely that one would make, use, or sell the Danzenbaker hive without knowing he was infringing, as certainly as Mr. Martin, the reader, and ourselves know it. It is, perhaps, a fact that we have done too little in the direction of introducing the new hive to the public.

Bee-keepers have been so writing us ever since our last issue of *The Quarterly* containing the more complete directions for properly making and using the hive, written by a thoroughly honest and unbiased friend. So far as our financial interest is concerned, which is by no means the paramount one, we have been in no hurry, knowing that time

would bring the truth uppermost, and feeling wholly secure in our patents.

There is also another phase to this subject. That strong sense of justice among bee-keepers, mentioned in your editorial, will very likely make it unnecessary for us to spend large sums of money in U. S. courts, provided the people are properly informed regarding the rights and wrongs of inventors, and it rests largely with our literature as to whether or not honey-producers shall receive such information.

JAMES HEDDON.

Dowagiac, Mich., Mar. 20.

In the meantime Mr. Danzenbaker was advised that Mr. Heddon would reply to his article then in type. In anticipation of this he directed his attorney at Washington to send in his opinion on the legal aspect of the question, to us. It was received before Mr. Heddon's article, and is reproduced herewith:

The A. I. Root Co..—Mr. F. Danzenbaker requests me to give you an opinion upon the question of infringement of the patent to James Heddon, for bee-hive, No. 327,268, issued Sept. 29, 1885, by such a hive as that shown in Mr. D.'s patent, No. 521,873, issued June 26, 1894.

A careful comparison of the hives shown in the respective patents discloses a similarity of structure only in the following respects; viz.: Each hive is composed of several (three) removable cases, containing respectively brood-frames and honey-sections, and each has a similarly made top or cover for the hive. Such similarity being found to exist, the question is presented, Has the Heddon patent any claim which, by a fair construction, can be held to cover the same, and hence be infringed by the Danzenbaker hive? In my opinion, this question must be answered in the negative.

The only claim of the Heddon patent, that even remotely touches upon the features of construction common to the two hives, is the 5th; but under no principle of construction, recognized by the courts, can his claim be held to be infringed by the Danzenbaker hive, because the latter does not contain the cleats and thumbcrews that are specified as essential elements of the combination in said claim. To infringe this claim, a hive must not only contain the thumbcrews and cleats, as the means for holding the brood-frames in position, but such screws and cleats must have substantially the location and relative position specifically defined in the claim.

The scope of this claim of Heddon, furthermore, is not only restricted by reason of its express limitations, but by the fact that the records of the Patent Office, in connection with his patent, show that he was not the originator of a hive composed of several horizontal sections, to enable the capacity of the hive to be increased or diminished according to the size of the colony. When his application for patent was pending, Mr. Heddon tried to obtain the following claim:

"In a bee-hive, a brood-chamber constructed of two or more horizontal separable and interchangeable sections."

This claim the Patent Office refused, as being to a construction that was old at the time of Heddon's invention, as shown by patents 33,668; 196,060; and 203,890, and the claim was accordingly dropped. You will see that this claim contains no such limitations as the 5th of his patent; and had he secured

the same, he could well assert the Danzenbaker hive to be an infringement. Unfortunately for Mr. Heddon, however, not being the *first* inventor of the subject-matter set out in said claim, he had to content himself with the 5th claim of the patent, with its limitations to thumb-screws and cleats, and he has no right to prevent others from making hives having a brood-chamber composed of two or more horizontal, separable, and interchangeable sections, unless they use in connection therewith the thumb-screws and cleats.

No principle of patent law is better settled than that, where an inventor in applying for a patent makes a broad claim, and drops it in view of its refusal by the Patent Office, and in its stead takes a narrow claim, having limitations to a construction not specified in the rejected claim, he can not be permitted to repudiate the limitations of his narrow claim, so as to make one an infringer who does not use what is specified in the claim, but uses only what was set forth in the claim originally made and dropped because of its rejection by the Patent Office. This is Heddon's position exactly.

In view of the foregoing, it is my opinion that, upon neither *legal* nor *moral* grounds can Heddon properly claim that he is entitled to stop the manufacture and sale of the Danzenbaker hive.

Washington, D. C. C. J. WILLIAMSON.

The 5th claim of Mr. Heddon's patent, referred to above, reads as follows:

In a bee-hive, a brood-chamber consisting of a series of reversible and interchangeable cases, each of said cases being provided with thumb-screws extending through one side, and with cleats at the corners of the other side and facing said thumb-screws, and of a number of reversible frames rigidly secured therein between said thumb-screws and cleats, and a stand and cover, substantially as and for the purpose set forth.

I have already sent for the copies of patents stated by Williamson to cover the divisible-brood-chamber idea; but at this date they have not arrived.

I desire to take no side in this matter, any more than to give each party a fair and impartial hearing.

EIGHT extra pages as usual.

THE two-pound vs. one-pound section question is very nicely answered by W. H. Putnam, in his paper in the Madison convention report in this issue.

Do not forget that now is the time to distribute the little pamphlet on bees and fruit, among neighbors who are disposed to call the bees a nuisance.

THE editor of *Review*, while admitting that the cutting-down of the labor item by the use of labor-saving hives helps to make a success of the business, says that, "if the flowers fail to yield nectar, all the short cuts in the world will not save us." Quite right, Bro. H.

WHEN a writer condemns a thing he has never tried, and speaks from his own standpoint, and not from that of another, and judges from his own climate, and not from that of another, his criticism is weak, to say the least.

THE February *Apiculturist* comes to hand with a smiling face and a cordial good will to all its sister-cotemporaries. It is largely, as are the preceding numbers, made up of editorial matter written in Mr. Alley's characteristic style.

THE editor of the *Review* agrees with me in thinking that Mr. Boardman is one of the keenest, brightest, and most intelligent bee-keepers we have. He is a man who writes but little, but thinks much. He has followed the bee-journals closely; and now that we have succeeded in getting him to write a few articles for GLEANINGS, I shall expect something unusually good from his pen. In this issue his articles are begun again.

CARDS are beginning to come in thick and fast, showing that there is a strong desire on the part of our readers for the continuance of the discussion, large vs. small hives. We have received only one request to have it dropped. So, unless the straws, or "sawlogs," point differently, we will keep up the question a while longer. It is a very important subject, and each bee-keeper should settle it in the light of the discussion brought out for his locality. Upon its right solution hinges largely the bread-and-butter side of bee-keeping.

A SUBSCRIBER writes that he likes our way of tiering up hives in the cellar for wintering, but he wants to know how to get rid of rats and mice. Our plan is none other than that used and recommended by H. R. Boardman; namely, piling bottomless hives, with cover sealed down, one on top of two others, so as to leave a large open space at the bottom. If the cellar is not mouse-proof, and can not be made so, use "rough on rats" or some other poison, nicely concealed in one or two kinds of food, as described by a correspondent recently. If there are only mice, the nicest way is to use common traps.

PERCOLATOR SYRUP A SAFE WINTER FOOD.

WE fed our bees last fall in two different ways. The majority of them were fed by the percolator plan, and the rest with syrup made in the old-fashioned way— $\frac{2}{3}$ sugar and $\frac{1}{3}$ water, by the use of heat. Although the former were fed with very much less labor, and with far less danger from robbers, and with no heat or mussing of pans or cans, they wintered just exactly as well. You see, the percolator syrup is made half sugar and half water. The bees receive it in a condition about as thin as nectar from natural sources. They ripen it thoroughly, and of course it is the best feed

they can have. I shall expect that, in a series of years, comparative tests will show that such feed is far preferable—that is, that thin syrup is much better than thick feed, either early or late.

THE HIGGINSVILLE AND GABLE COVER MIXED.

It appears that some of the correspondents of our exchanges, in criticising the Higginsville gable cover and the ventilated gable cover, have got the two mixed. It is perfectly evident that they have not studied carefully the engravings and descriptive matter of each cover; otherwise they would not make such blunders in their criticisms. The ventilated cover is intended primarily for the South, and all climates where the sun pours down hot. It is not a cover that I would personally use, as I prefer a single-thickness cover, flat on the under side; but as all people can not be made to think alike, and as climates vary greatly from each other, manufacturers try to make covers that will suit all classes and conditions. Why one should condemn one style and praise another, I can not understand. One might as well condemn climate.

DO BEES TRANSPORT EGGS?

CONSIDERABLE speculation is now being indulged in as to whether bees ever transport eggs in their hive. Most authorities in this country seem to agree that they do. So far as I am concerned I know that they do, for I have seen them carry eggs—not once, but a number of times, and I do not understand why our good friends the Germans have not seen a similar thing. Mr. Hasty, in commenting in the *Review* on the fact of my having witnessed the transportation of the egg, says I “neglected to follow on and see whether the egg was used for lunch or queen-rearing, or what.” This is true; but I was not then particularly interested in the point, because I assumed that the mere fact that they carried them at all was evidence that they intended to use them in some queen-cell. This they may have done, but I feel tolerably sure that bees do at times use them for “lunch,” for I have repeatedly noticed, as have others, that, when I have put a frame of eggs into a colony, for the purpose of obtaining queen-cells, two or three days afterward a large portion of the eggs would have disappeared.

HASTY ON GLEANINGS.

THE following very kind notice is from one of our old correspondents—Mr. E. E. Hasty:

Let me see; what kind of paint did I put on GLEANINGS the last time she was in dry dock? Whatever coating got put on for some of the promising writers seems to have peeled off since. I was going to name John Smith as a “peel-offer;” but Jake, after sleeping in his bunk for many months, has been on deck quite recently. But if there is a little peeling off occasionally, GLEANINGS is the same nice ship—same assortment of captains and

pilots, and same boa's'n. And she rides the waves of the hard-times cyclones a little easier than any other craft. No other seems to be saying, “Eight pages extra this time.” The editorial work in the line of travel notes and interviews keeps well up, if not expanding a little in space. Friend Norman seems to be the new “middy,” with more frequent hearings from friends France and Dayton. Portrait-publishing, which had declined a little, is being revived. The opening number of the year has two excellent portraits; and the persons are people of general interest whose pictures have not been trotted around much if at all. They are John T. Calvert, of the A. I. Root Co., and N. E. France, of E. France & Son. And putting footnotes of the GLEANINGS variety on the Straws gives an added vivacity to the first page of late.

Coming from such a source, it is highly appreciated, and we tender friend Hasty our sincere “thank you.”

WINTER LOSSES.

OUR wintering loss up to the 20th of March was only 2 per cent, out of a total number of over 200 colonies. Three of the colonies were made up of a number of small queen-rearing nuclei, united late in the season. Such made-up stocks are liable to succumb any way, so we always take our chances on them. The other colony was one of those handsome five-banders.

Winter losses among careful and expert beekeepers this winter will be comparatively light; but among the slovenly and slipshod it will be heavy. It seems to be a fact that cold winters (that is, continuously cold), where the beekeepers are of the class first mentioned, are favorable. The bees do very little brood-rearing, and the spring usually comes on quick, and opens up warm and balmy. As I have often remarked, it is not as difficult to *winter* bees as it is to *spring* them. Well, then, if the winter suddenly turns into good warm spring, as we *hope* it will do this spring, and as it generally does do after such a cold winter, this spring will be comparatively easy on the bees. There! I am afraid I am counting the chickens before they are hatched.

NON-SWARMING DEVICES AND FIVE-BANDERS.

EXPERIMENTER TAYLOR, in the *Review*, in referring to non-swarming devices, says, “One can hardly avoid the suspicion that the Langdon device and the Conser hive depend for their success upon principles which the bees are by no means uniformly careful to observe.” From all I know regarding these non-swarmers, I think Mr. Taylor is about right. Further on, referring to the five-banded bees and his experience with them, he says:

Though called “golden Italians,” I should have pronounced them any thing but Italians, judging from the disposition they exhibited. While they are not the most irascible of bees, they are yet very nervous, and quick to manifest a recognition of intrusion, from which characteristics I should have

judged them to be largely of Syrian blood. But the most noted characteristic exhibited by at least one of the two colonies was an inclination to rob. If there was any attack to be attempted on a colony, or any chance to pry into a case of honey, about one-half the would-be thieves out of a large apiary were from one or both of these colonies. It is to be hoped that this peculiarity may stand them in stead in the gathering of nectar when an opportunity occurs.

I can personally vouch for the truth of Mr. Taylor's statements; for while I was in his apiary last summer they exhibited several of the characteristics he has pointed out.

THOSE GIANT BEES OF INDIA.

PERHAPS our readers will remember seeing in our columns an advertisement of "Giant Bees." We accepted the card for two insertions, and in the mean time wrote to the advertiser, asking him to send samples of the bees, as it is not our custom to accept an advertisement of a novelty unless we know what it is. We received no response to our first request, and finally wrote again, and still the request was ignored. We dropped the advertisement, and finally the following card came to hand:

I have been led into the Giant-Bee business through my ignorance, and am out \$14 cash. I should like to have you discontinue my advertisement. I have received a good many letters and postal cards asking for descriptions, samples, etc., but no orders or money. If I receive any it will be returned at once. I have answered none of them yet, and am very much ashamed of having been mixed up in this matter. C. D. HOLT.

Murray, Ky., March 12.

Inasmuch as Mr. Holt claims, in the *American Bee Journal*, that the drones of the "Giant" bees will fertilize queens in confinement—yes, several of them—even in a queen-cage, it is evident he could not be fully informed in regard to the habits of bees or of the experiments that have been made in the past. We should not have inserted his advertisement in the first place; and it is due to our readers and Mr. Holt's patrons that his card should be published.

I do not mean to give the impression that Mr. Holt intended to be dishonest; but it is a little singular that he refused to send samples of the bees or reply to those who wrote. If he really has the bees, and inasmuch as he has advertised them, it seems to us he ought to be willing to send at least the editors of bee-journals dead specimens, even if it is difficult for him to get live ones at this time of the year. The \$14 that he refers to is probably the total cost of advertising in all the bee-journals.

WAX ADULTERATIONS, AND SIMPLE METHODS FOR DETECTING THE SAME.

SINCE our last issue we have been carrying on quite a series of experiments, taking wax of known purity, wax adulterated with paraffine,

and wax mixed with ceresin, and carefully noting the results in each case.

I procured a lot of test-tubes, such as are used by chemists, and told the foreman of our foundation department to put a small quantity of each of the samples into each tube. These, together with a thermometer, were to be placed in a bath of water, the temperature of the water to be gradually raised, when he was to be careful to observe the melting-point of the contents of each tube. The different tubes were numbered, and the results are shown in the following table:

No. 1, white wax, commenced melting at 156° F.; entirely liquid at 160.

No. 2, half wax and half ceresin; commenced melting at 160; entirely liquid at 166.

No. 3, red wax, probably Southern; commenced melting at 152; entirely liquid at 158.

No. 4, recently bought wax, commenced melting at 153; entirely liquid at 159.

No. 5, ceresin only, commenced melting at 163; entirely liquid at 172.

No. 6, half wax and half paraffine; commenced melting at 140; entirely liquid at 148.

I will explain that No. 3, the red wax, is a product from the South or from Cuba, the real color of which is a brownish red, and at first it appears to be suspicious; but, as I shall show later on, it is probably all right. Nos. 1, 3, and 4 are probably pure wax. The slight difference in the melting-points is due to the amount of dirt, or whether the wax had been recently remelted often or not.

Now, then, referring to the table you will see that the pure wax begins to melt at from 152 to 156, and becomes a perfect liquid at from 158 to 160. You will observe that No. 6 (wax that we adulterated ourselves) half paraffine and half wax, commenced to melt at 140, and became liquid at 148. No. 2, half wax and half ceresin, commenced to melt at 160, and became liquid at 166. No. 5, pure ceresin, began to melt at 163, and became liquid at 172. We therefore observe that the melting-point of ceresin is much higher than that of wax, and that paraffine is correspondingly lower. No. 6, half paraffine and half wax, shows the melting-point just where we should expect it. No. 2, half wax and half ceresin, shows figures that are half way between the pure wax and pure ceresin. You see, therefore, that something can be told by the melting-point of doubtful pieces of wax. I wish to remark right here, however, that the text-books put the fusing-point of wax anywhere from 145 to 150. This, doubtless, applies to wax as it comes from the hives, and which has not been rendered previously. It is observable that, the more wax is melted over, the higher the fusing-point, and the tougher it becomes.

Now, then, I want to give you a simpler and easier test, and one that may be, I think, fairly reliable. In our last issue we quoted from

Cheshire, giving the alcohol test. But he seems to assume that it is valuable only for the detection of *grease*; but we find that it will apply not only to grease, but to *wax* and *paraffine* as well. We procured a large Mason jar—one holding two quarts; and in the bottom were put several pieces of wax of known purity. Water was poured in, to a point say half full. Of course, the wax would all rise to the top. Alcohol was then added until the wax had settled to the bottom; then we took a piece of No. 6, half paraffine and half wax, and found that it floated readily; also a piece of No. 2, half wax and half ceresin, did the same. Pure paraffine and pure ceresin seemed to be more buoyant on the surface of the liquids, as a matter of course. Later on we took a sample of wax containing 10 per cent only of ceresin. It hovered nearer the top of the liquid, but did not seem inclined to come entirely into the "bad company" of the pure ceresin and pure paraffine, and the mixtures, 50 per cent of each.

The alcohol (or specific-gravity) test is not entirely reliable, but sufficiently so to put the wax-buyer on his guard, and cause him to have a chemical analysis made. I think there is no question but that the mixtures of half ceresin and half paraffine can be readily detected by the above test; and it is to be assumed that, if adulteration is practiced at all, the mixers will put in at least 50 per cent of the cheaper article, and that, likely, would be either ceresin or paraffine.

These experiments were performed in my presence by our Mr. Kindy, foreman of the wax-working department, and Mr. Karl Rudolph Mathey, who, I found, is quite an expert in the wax business. He tells us that the Germans make ceresin foundation, two-thirds ceresin and one-third wax—that is, they sell it for what it is; but from what experiments we have made, I am rather of the opinion that the bees will not work this article nearly as well as they will pure wax; indeed, we find it impossible to roll foundation from *pure* ceresin. It is too hard and brittle, and is lacking in that ductile quality so necessary in hive-work, and would not, I imagine, be very suitable in the hive, even when mixed with pure wax.

The ordinary paraffine of commerce has a beautiful milky whiteness, and, as explained, it has a lower specific gravity than pure wax. It is more ductile, and has a lower melting-point. Ceresin, in color, may be milky white, or so nearly resembling the color of wax, as to deceive the most expert, from its mere appearance.

We are now buying our supply of wax through a New York inspector, who has made this business of sifting the adulterated from the pure almost a life-study. To give you an idea of how the fakirs are trying to palm their adulterated goods off on the unsuspecting, let me give you an instance. Out of 23 sacks of wax that were inspected by him, only 17 were ac-

cepted, and were subsequently shipped on to us. I can hardly think that any of the foundation-makers have been deceived. The adulteration of wax has seemed to spring up within a year; and I trust that the simple tests above given will assist our co-workers or others to "spot" the spurious at once.

ROOT BROTHERS' HOME REPAIRING OUTFIT.

LET me explain, to begin with, that the Root brothers are no relation to A. I. Root. That is, they are no relation without going away back. Their celebrated repairing outfit was first worked up by George A. and C. F. Root, in the middle of the year 1890; and I remember of being greatly pleased to see the unique engraving of the cast-iron lasts, clinch-nails, etc., when they first put it out upon the vaxed. You now can readily understand how vexed I felt when I saw unscrupulous imitators come out and copy even their advertisement before the idea had been out in print much more than a year. One of the first men to copy their idea entire, without so much as saying "by your leave," was one John H. Grant, of Chicago. I have had in mind, for a year or two past, holding these imitators up to public gaze; but I finally decided that the man who would appropriate ideas would, sooner or later, take other things, and so I let him alone, thinking it was not really my affair, any way; but the paragraph which I give below, from the *Rural New-Yorker* of March 9, seems to open the way to give Mr. Grant a little free advertising. Read it, and then give the gentleman a wide berth.

There may be a less satisfactory business man in this country than John H. Grant, of Chicago; but if there is, the *R. N.-Y.* has yet to find him. We contracted with him recently to furnish a kit of tools for our subscribers, at a certain fixed price. When we sent him the orders, he shipped about one-half the tools promised; and when we complained, he assured us that we had made a mistake—that he had two sets of tools, and that he had given us prices on the small kit. His story seemed plausible, and we accused ourselves of a blunder, and told him to send the rest of the tools at our expense. We also ordered the large kit sent to 27 more persons. This he promised in writing to do at once, six weeks ago, and sent us a bill for the same. We then supposed that he had sent them; but finding that the tools were not delivered, we kept writing to find out why. He now has the impudence to write that the orders are not filled, and that they will not be until we comply with unreasonable demands, which he now mentions for the first time. Fortunately, we are able to get the tools elsewhere, and we have sent the orders to another factory, where they will be filled promptly, and where we will get our future supply. This explanation seems due to the subscribers who have been so long and patiently waiting for the tools which they should have received weeks ago. All the orders will now be forwarded at our expense to those who received only a part of the set. The full set will also go promptly to those who have received none.

SACALINE—THE NEW AND WONDERFUL FOR- AGE-PLANT.

I find that much interest seems to be centering in this new plant. I have already seen it growing at the Florida Experiment Station, at Lake City. While it does certainly promise a good deal, the statements we find in the seed-catalogs are, without question, greatly exaggerated. As an illustration, the following is copied from a circular, with cut:

Is perfectly hardy, even in Siberia—Flourishes in the Indies.
Requires no plowing before planting.
Needs no cultivation, no manuring, no replanting.
Roots penetrate deep into the soil.
Once planted, stands for ever.
Endures severest drouth with impunity.
Grows in poorest soils. Luxuriates in wet lands.
Thrives where no other forage-plant will grow.
Young shoots and leaves eaten as a veg-table.
Stems and leaves, green or dry, greatly relished by cattle, sheep, and horses.
More nutritious than clover or lucerne.
Gives three and four cuttings per year.
Produces 90 to 180 tons of green forage per acre.
Grows 14 feet high by June.
Excellent soil-enricher. Planted at any time.
Affords shade to cattle in summer.
Protection against storms in winter.
Floods will not destroy it. Fire will not kill it.
Cattle can not trample it out.
Seed has been sold at \$100.0 per pound.
Indorsed by the highest authorities.

stock is limited. Some who have tested it claim that their stock will not eat it. This may be because they have been too well fed. It may be, also, that they have not learned how, or have not acquired a taste for it. The wild cattle in Florida will not even eat corn meal or bran, without "learning the trade;" and a cow that is dying with starvation would die all the same if ears of corn were all around her. Under very favorable circumstances, the plant may grow from 12 to 14 feet high, and so will a good variety of field corn down on the rich corn-bottom land of Missouri—at least, it comes pretty near that. The claims, however, of "90 to 180 tons of green forage per acre," I should say, are away off—that is, if we are to understand by the above that this enormous product will be eaten by "cattle, sheep, and horses."

You will notice the plant is said to be hardy from Siberia to the Indies. Well, when I saw it in Florida, toward the first week in March, the growth of last year was all killed down to the ground—killed, I suppose, by the frost; but new shoots had started up, some of them a foot away from the original plant. These shoots were from 3 to 6 inches in height. By permission I picked some of them, and felt certain by the taste that all kinds of stock will eat it—at least, in this stage—and I also think it likely it might be cooked like asparagus. As to whether one would want to eat it unless he was very hungry, will have to be tested by experiment.

SACALINE (*Polygonum Sachalinense*) THE NEW FORAGE AND HONEY PLANT.

It will, without doubt, grow from 6 to 10 feet high in a season, on any tolerable soil, when well started; and I believe cows and horses will eat it to some extent when it is young and tender, especially after they learn how. In this respect it is something like sweet clover. It takes a year or two, if I am correct, for it to get firmly rooted. After that it makes this tremendous and extraordinary growth. We can furnish the seed in five-cent packets, but

Last, but not least, there are reports floating around that sacaline is a great honey-plant. I can not find out any thing very definite in regard to it. There do not seem to be any "posies" in the picture, but perhaps the plant had not got quite tall enough to bear honey when the photograph was taken.

We will give further reports in regard to it as soon as we get hold of any thing really authentic.

ELECTROPOISE, OXYDONOR, ETC.

THE "BLIND LEADING THE BLIND."

Beware of false prophets, which come to you in sheep's clothing, but inwardly they are ravening wolves. Ye shall know them by their fruits. Do men gather grapes of thorns, or figs of thistles?—MATT. 7: 15, 16.

Electropoise has been imitated. Just think of it! Somebody, excited by the idea of getting \$25.00 for what costs about as many cents, has copied *Electropoise*! The new machine is advertised, with the names of twelve ministers of the gospel to back it—at least, they have got "Rev." before their names. The thing is more cheeky than even *Electropoise* itself. It also claims there are many imitations. It will not only cure people, but it will make *plants* grow. The picture of it is so exactly like that of the *Electropoise* that you can hardly tell one from the other. Price \$25; or you can rent it for \$3 a week. They admit there is nothing inside of the little metal case except sulphur and carbon. I really do not understand why people can not copy it and make one themselves. But the manufacturers say it is "combined in certain delicately adjusted proportions." Here is a sample of their reasoning. To show how this machine takes oxygen from the air and transfers it to the body:

We take from page 8 of Oxydonor circular:

HOW DOES IT CURE?

Electricians have known for years that any body connected with the earth by means of a conductor, like a wire, soon becomes "negative."

A square and positive untruth in the outset. Nothing whatever passes along the wire under the circumstances mentioned.

The earth attracts the positive fluid from the body; and as all bodies have both positive and negative electricity in them, when one is withdrawn the other remains.

Another untruth.

We now know that difference of temperature lies at the bottom of this transfer. Hence, if the little plate of the "Oxydonor" be attached to the ankle, and the metal cylinder—or "vocol"—be placed in a temperature colder than the body (as in ice, cold water, or air), the positive fluid leaves the body and goes to the colder substance, thus leaving the body "negative." So much is plain.

Exceedingly plain, Mr. Oxydonor; by supporting the human body, or any other body, on a stool with glass legs, or insulating them in any way, this insulated body may be made either positive or negative, by means of a suitable electrical machine. But the idea that human bodies, or any thing else, becomes positive or negative when standing on the ground uninsulated, is a simple absurdity, even if it is quoted over and over again by venders of quack medicines.

Now, we are surrounded by the air, four-fifths of which is free oxygen gas, and—

Now, I do not know whether this is a sort of typographical blunder, or whether it is part and parcel of their other *awful* misstatements. We have given them the benefit of the former. Common air is about one-fifth oxygen and four-fifths nitrogen. See under "air" in Webster's dictionary. But let us now take the last half of the sentence.

—oxygen gas has a strong affinity for the negative state.

One begins to be puzzled a little as to what they mean by a "negative state." If they mean electrically negative, then it is another stupid falsehood. Oxygen has no more attraction for a body negatively electrified than a horse has for a snapping-turtle. One statement would be just about as sensible as the other.

Therefore, because you are connected with a colder substance, because that colder substance draws the positive fluid from you, thus leaving you "negative," because the air is touching your body at all points, because the oxygen of the air is free, and has an affinity for the negative state—you absorb the oxygen in the skin and tissues. The colder the substance with which you are connected, the more rapid the transfer of positive fluid, the stronger your negative condition, and the more intense the absorption and action of the oxygen.

This last scientific (?) explanation of the way in which Oxydonor works is just like what I have quoted above. There is just as much science to it as there is in the ravings of a maniac.

Now, if any of you think A. I. Root is making a mistake, and that he is doing injustice to an honest invention, find an educated man, if you can, who can make any sense of the above quotation. A good man may pass counterfeit money by mistake, not knowing that it is counterfeit; but the man or men who *made* the counterfeit money did not make a mistake. And the men who make *Electropoise* and *Oxydonor* did not make a mistake. They *knew* they were humbugging the people by lies; and the men who put up this little metal case, filled with sulphur and graphite, know that it has no virtue, exactly in the same way that the counterfeiter who is at work with his counterfeiting-tools knows the money he is making is not genuine and honest. Quite a few who use the machine are now admitting that it is not electricity, but they claim these people have discovered some new and heretofore unknown force or agency for the cure of the disease. My friends, if a new force in nature had been discovered, the whole scientific world from the Atlantic to the Pacific would be in an uproar about it. It would be of a thousand times more importance than a new planet, comet, or any thing of the kind. But the truth is, scientific men and scientific journals know nothing of any such discovery, for no such discovery has been made, in fact; and yet we have a case where a schoolteacher is taking the thing into a school and teaching the pupils that it is a scientific instrument! Again, they are making an excuse for charging \$25 for a thing that costs only from 40 to 50 cts., by saying that it is customary nowadays. Everybody who is charging more for a book than it is really worth, or for some secret in agriculture, or for some cure for disease, seems to have got hold of the following story. I will give it briefly in substance:

A big factory was standing still because they could not make the engine work. They telegraphed for a man, and with two taps of his hammer he made it all right, and took the next train back to his city home. His bill was \$25.25. When asked to explain, he said the 25 cts. was for doing the work, and the \$25 was for knowing how.* Now, a great many people are repeating this, and thinking it is the honest truth. I want to say that I have never met with such a case in all my experience, nor any thing like it. We get experts from the large cities, to teach us how to do any thing we want done, or to make plans for us, etc. They charge us for only their time and traveling expenses; and we seldom pay a man more than three or four dollars a day.

While in Orlando recently, a subscriber of *GLEANINGS* told me that his pastor's wife had recently purchased an *Electropoise*, and, like

* Quite a compliment the above story pays to the ability and skill of the engineer placed in charge of the engine belonging to a great factory. I rather think our engineer would smile somewhat to see a city chap—one of the know-how sort—doing things after that fashion.

all the rest, she thought it was doing wonders in the way of improving her health. My friend heard of it, and gave his minister, who is a Congregationalist, a copy of our journal. He read it carefully, and what do you think the verdict was? Why, he spoke out square and honest, as any educated minister of the gospel must speak. Said he, "Why, Mr. Root is right about it—unquestionably right. There is no possibility of his being mistaken." It is this way: Sense and reason stand back of even *personal experience*. Two and two make four—always have made four, and always will. Now, somebody might as well say that two and two make five, and that they know it by personal experience, as to say these things cure disease. We need a shaking up, all of us. If sense and reason can not be made to come uppermost, we had better go straight to an insane-asylum—the whole lot of us.

OUR HOMES.

As I sit down and think of the two pleasant months I passed away down in those Florida homes, not only pleasant memories, associations, and recollections come up, but there comes also a feeling that God *called* me to go down there, and that it was his purpose to teach me some valuable lessons. I am going to try to tell you one of them. During all of those two months I was an *invited guest* in somebody's home. Sometimes the invitation came about in a strange way—I might almost say in a mysterious way. You know—

God moves in a mysterious way
His wonders to perform.

Well, I was, as I told you, an invited guest almost every day and every hour. It was quite an abrupt change from many business cares to a life of ease, and of being ministered *unto* instead of ministering to others. Here at home, with my many responsibilities and more or less things constantly going wrong, which I must set right, it is not very strange that I get into a way of—well, we will say of remonstrating when people are thoughtless; and I am afraid sometimes that I am not just as kind and courteous to imperfect humanity as you might judge by my talks and teachings. I hardly need tell you that, when one goes "visiting," and accepts an invitation, he is, at least for the time being, on his "good behavior." He is not to complain, no matter what unpleasant things come up. Why, the man or woman would be a churl indeed who would scold and find fault while a guest in the home of somebody else. Let me make haste to tell you, however, that I did not, during all my trip, find any thing to scold and find fault about. Some accidents happened. It was unexpectedly cold in Florida, and they were not prepared for it, and I had to take my share of putting up with every thing as we found it. But I did not find any thing to complain of nor to feel cross about. You may be surprised when I tell you that I really *can not remember* of having spoken an unchristianlike word during that whole trip; and I can almost say that I did not have an unchristianlike feeling. It surprises me when I think of it. Is it really possible that A. I. Root passed two whole months of his life without being what you might really call wicked, or having a wicked or unchristianlike thought? There must be some explanation for this. There is an explanation. When the time came for me to leave for home I did not really want to go. Perhaps I felt something as Jonah did when he was com-

manded to go down to Nineveh. I was not called, however, to go down to Nineveh to *preach*, and I did not do any preaching, unless, indeed, I did something that might be called preaching on that one particular Sunday I told you about. One great secret of this wonderful change and transformation was that I asked God for grace in the very outset. I felt afraid that I should, by my abrupt or restless disposition, hurt somebody's feelings. Therefore, when I started out I prayed earnestly for grace to do my work *well*, whatever work it should be. It does not seem to me that I did very much work after all of *any* kind. In fact, in one sense it does not seem to me that my visit amounted to any thing—that is, so far as doing any particular good is concerned. In another sense it amounted to something wonderful, for I met kind friends, a host of good, bright, intelligent, earnest men and women, who "loved righteousness and hated iniquity;" and I felt again and again, as I bade them good-by, "Why, I would not have missed knowing these good people for any thing in the world." They taught me great lessons, and, I presume, without *thinking* how much good they had done me. I verily believe that the thought of that Florida visit will make my heart bound until the last day of my life. I love our nation of people better than I have ever loved them before; and I love God more for having given me these pleasant glimpses of *other people's* "homes."

Circumstances and events seem to have strangely crowded me, or pushed me, as it were, into the very inner lives of many people. One of the pleasantest calls I made was where I visited a bee-keeper away off in the wilderness, expecting to call just one brief hour. I was taken sick, and it was not thought best for me to ride back through the woods, in the cold. You see, it was during the February freeze. I did not get any better, and I was obliged to stay several days. Sickness and suffering finally obliged them to take me into the very inner circle of their little home in the woods. As the man and wife were, however, professing Christians, we did not have a very *hard* time in getting along together. One of the days was the Sabbath; and as I was really too sick to sit up much I leaned back in an easy-chair and we exchanged religious experiences, read from the Bible, and sang Gospel Hymns. Again and again my thoughts go back to this brother and his good wife; to that little home with its bees and chickens and garden, and the dainty little spring beside the babbling brook under the palm-trees but a little way from the house.

Dear friends, do you not remember how often we see inscriptions, not always in the cemetery, where they commence, "Sacred to the memory of ——" and then follows the name of some dear departed one. I think it must be God's Holy Spirit that has been suggesting to me that we need not *wait* until our friends are dead and gone before we erect a little shrine in our hearts, "Sacred to the memory of —," somebody who is yet full of life; and I have taken great joy and pleasure in thus erecting a host of little shrines stowed away in the little corners of my heart, "sacred to the memory of" the Florida homes I have visited. I might think these friends did not enjoy my visits as I enjoyed them, were it not for the postal cards and letters that keep coming now—reminiscences, as it were*. Then I fall to wondering if, in my

*Here is a brief extract from one of the postals:

We all feel the better for your coming; and all join in sending you our best wishes. Come again, please. Surely "goodness and mercy" have "followed" you these many years. All the bee-world will say amen.

awkward way, I may not have given some good brother or sister pain by my carelessness. If so, I wish to assure such that I did not mean it, or did not intend it.

Just a little more about that lesson God wanted to teach me. Several times I met people with whom we had had little differences. Sometimes it was some one whom our people had refused to send goods to because they did not know all about them. In one case a veteran bee-friend, and one of the shining lights in bee culture, moved from Iowa away off down to Florida, and did not tell us he had done so—that is, when he made an order for something, just in the way he was in the habit of doing away back in Iowa, he forgot to tell us he was the same man, down in Florida. Had the clerks come to me with the order, I should have known our old friend at once, even if he was down in Florida; but in this case he not only overlooked our blunder, but he hailed Constance and myself as we were on the way to a hotel, and gave, as an excuse for so doing, that their weekly paper had already announced in plain print that we were staying at his home. When I looked astonished at such a procedure he good-naturedly replied, "Why, Mr. Root, didn't you know that obituaries are often written before people are really dead?"

When the letters of invitation came, asking us to go to certain points, I did not always know any thing about the people; but the fact that they wanted me to make them a visit was sufficient; and I never inquired, and scarcely ever thought about, what particular church these people belonged to, or whether they belonged to any church at all. The result was, I visited people of various denominations, and was taken right into the homes of people who represented almost all kinds of belief. Sometimes I laughingly suggested, when the family Bible was handed to me, that perhaps I was not used to conducting worship in their way. The reply was, invariably, "Brother Root, we will worship God this time in your way."

The matter of giving thanks at the table, I found, is also conducted in quite a variety of ways. Sometimes I did not readily "catch on," but I really believe that one of my pleasantest experiences was in having some good brother or sister, in a most kind and friendly way, explain to me their ways, or the forms in use by their particular denomination. Are you surprised that I began slowly to have a broader charity than I had ever had before? One very pleasant visit was with a brother who did not profess any religion. He told me at the outset that we had better not discuss theology, because we would only get mad.

"Oh! no, dear brother, we shall not get mad—I'm most assuredly shall not."

"Oh! yes, you will get mad if I tell you the plain truth. If you do not, you will be the first Christian I ever met who did not. They get mad, every last one of them, when people of my class come right out and take the liberty of believing what we choose, and telling the truth in plain English."

Then he told me of some of the things he had said to ministers, and the reply that the minister gave. Now, I am really afraid that, before I made this visit, I should have said the minister did about right. But I think now he made a mistake. You see, I was an invited guest; and, besides, I had given a sacred promise—at least it was sacred to me—not to get mad. My friend with whom I was riding said some severe and cutting things about our faith; and, oh I am so glad that I replied gently and mildly. This friend recommended books and writers who speak disrespectfully of the Bible and of the Christian religion. Of course, I could not agree with him here.

Well, the next day as we were riding away off through the great pine forests we called at a humble home where there was quite a flock of children, and not very much for them to read. My companion said he had brought along a bundle of papers for the family, and in some way I got it in my head that he would naturally bring them something that might teach disrespect to Christianity; and if so, I felt like making a protest. How do you suppose it turned out? Why, dear friends, that bundle of papers I had been looking at suspiciously turned out to be some old worn copies of—what do you think? *Gleanings in Bee Culture!* I asked God to forgive me for my uncharitable thoughts; and when I reminded my good brother that the Home Papers in those back numbers would teach the children Christianity, he looked up with a laugh, and said he believed he would rather risk the children with such teaching than any thing else he knew of, even if a good deal of it was fallacy and superstition. O dear friends, I am sure there is something wrong in having such wide differences between God's people and those who do not see things as we do.

At another home I found they belonged to a sect who worship God on the last day of the week, instead of the first. But my heart had been considerably mellowed by this time. I assured the brother who came for me Saturday night, that, had I known of his religious convictions, I should have greatly enjoyed worshipping with him on his Sabbath instead of mine. Then I should have been obliged to have two Sundays, some of you may suggest. Not necessarily. He lived away back in the woods; and while I was his guest I could have done as he did, without any violence to my honest convictions.

The great Father, it would seem, had still another experience in store for me. I was obliged to hire a livery, to be taken five or six miles to the home of one who had given me an invitation. The liveryman said I would find "my man" at a camp-meeting of Spiritualists, for he was one of the leaders. I found him just a little before the meeting opened. In fact, there were other bee-keepers present also with their families. Would I care to attend one of their meetings? Yes, I told them I should be glad to. Dear brother or sister, if you should feel like criticising my course, let me say that the earnest follower of Christ Jesus can go anywhere unharmed if he holds fast to the strong arm of Him who once said to the winds and the waves, "Peace, be still." The speaker's stand was spanned by a beautiful arch on which was the text, "Peace on earth, good will toward men." The hymns that were sung were such as we generally use in our places of worship. The music was most beautiful. A bright young daughter of my friend played the violin, and another bee-keeper's daughter played the guitar. In a little time it was announced that the address would be made by a speaker who would speak on any subject that any one of the audience might suggest. I was called upon to furnish the subject. After asking the Holy Spirit to guide me, I wrote on a piece of paper, "Thou hast loved righteousness and hated iniquity." Two other subjects were given the speaker, and I believe that, in his address, he included all three; but in order to reach the train I expected to take, I was obliged to leave the tent before the discussion was ended.

I have found it a pleasure to do business with your firm, as goods are always carefully packed and promptly sent.

Portland, Ind., Feb. 25.

WM. N. STOUT.

FLORIDA FOR HEALTH.

Before I go any further, I think I must answer a few questions in this line. When I left home, I was suffering from a severe cold that had settled into a kind of bronchial trouble, that has followed me more or less winters ever since I was away up in Portland, Ore. After being in Florida three or four weeks, this entirely disappeared. My appetite greatly improved, and I was particularly impressed with the fact that I could sleep better than I had been able to for years. I used frequently to ask the privilege of going to bed when it was only eight o'clock in the evening, and I often slept soundly until the sun was up and shining in my face next morning. This is a new departure for A. I. Root. During the last four weeks I was in Florida, as a consequence of this, I learned to omit entirely my naps in the middle of the day. Since I have been home I have been feeling more vigor and strength of mind and body than for years past, unless, indeed, it was when riding the wheel. I can not ride my wheel now here in Medina, for the roads are too muddy.

Well, you will find people all over the State of Florida who went down there to live because they could not live anywhere else; and quite a few say they came without any expectation of living many months *anywhere*. I do not know whether it is the beautiful climate, or whether it is spending so much time sitting in a rocking-chair on the veranda, or whether it is the general fashion of taking things easy, that makes people get well and strong in Florida; but I have been told many times that careful statistics show the death-rate according to population to be less than in any other State in the Union; and this, too, right in the face of the fact that the State is the general rendezvous for invalids from all over the world. If this is true, it is something really remarkable. By the way, I want to say, too, that I did not once feel a bit of my old nervous prostration. I got around lively every day, as I do anywhere else, and enjoyed lots of energy, strength, and enthusiasm during the whole time. I was told several times that nobody ever has grip down there—at least, in the southern part of Florida; catarrh is also almost unknown. Some eight or ten years ago a young lady worked in our office, who was quite deaf. She finally went to live with a brother at Sorrento, Fla. Most of you remember Nellie Adams, who used to advertise queens from that point. When I met her I expected I should have to shout to make her hear; but as I noticed she heard every word of the most commonplace conversation, I said, "Why, look here, Nellie, how does it come that you are hearing every thing we talk about? What great doctor brought about this cure?" She replied in substance that she had reason to believe it came about from living in Florida. When she was here in Ohio, she was troubled with catarrh, which became so bad that it affected both her hearing and speech. She noticed her trouble began to improve almost as soon as she arrived at her Southern home, and it finally disappeared entirely. Since then she has been North, and stayed a whole year at a time, but she hears perfectly.

Now, friends, before spending very much money with doctors or medicines I would try at least a few weeks in Florida; and by all means try Florida rather than Electropoise, or

anything else of that ilk. If you have not very much money, you can rent some sort of domicile very cheaply, and you can get along down there as economically—that is, if you are so inclined—as in almost any place in the world. A great part of the year you do not really need any house at all, except for the looks of the thing; and if you do not care to put on much style, food and clothing may be had for a very small sum, comparatively.

It occurs to me that I may have put the matter of health pretty strongly in the above, and perhaps it may be no more than fair to say that a great part of Florida is occupied by people who have taken up homesteads. They have 160 acres of land, but they really make use of not more than five or ten acres—that is, a great many of them do this way, and every homesteader is anxious to have neighbors. He would sell five or ten acres very cheap—sometimes he would give it away in order to have somebody move in and start a settlement. There are lots of towns—that is, they are towns on the map—in Florida where there are not any houses at all. At Gifford Station, for instance, which is to be seen on the map, there are no houses, not any station, nor even a platform—no, not even a crossroad. There is a sort of road that runs parallel to the railroad, and the town is supposed to be somewhere on this parallel road. Well, you see people are very anxious to have towns built up, because that would advance their property. They are interested everywhere in having people move in, and, as a natural consequence, they are all the while studying up the advantages of their locality. This is good, and I am glad of it; but it has a tendency to make everybody honestly think that *his* locality is an *exceedingly* healthy one. I was led to believe there might be some honest bias in their opinions, because so many will say, "Oh, yes! over at so and so it is *sickly*. They have malaria and fevers;" and at some other place they will tell you that there are mosquitoes, fleas, etc., so that a body can hardly live; "but where we live you don't have any troubles of this kind. See how well I am. There ain't anybody sick anywhere in this neighborhood." I did find people sick, however, in some places, but it was mostly rheumatism. Even Florida does not seem to be proof against some kinds of this dread disease.

DEATH OF MR. HENRY NEIGHBOUR, SENIOR

MEMBER OF THE FIRM OF GEORGE
NEIGHBOUR & SONS.

The above announcement comes in the *British Bee Journal* for Feb. 28—another reminder that the veterans in our industry are passing away. For more than a quarter of a century the name of George Neighbour & Sons has been almost a household word in apiculture; and notwithstanding the criticisms that dealers in apicultural implements are pretty sure to get now and then, I can not remember that I have ever heard a reflection cast on the business methods of the above-named firm. Their dealings, and their whole lives, in fact, seem to have been characterized by a sort of manly integrity and gentlemanly bearing that it would be well for us to imitate on this side of the great water as well as the other. Perhaps it would be well to mention that one of the standard works on apiculture in England comes from this same firm. A. I. R.

SWEET-POTATO SEED

Yellow Jersey (the best), Red Bermuda, and Yellow Nansemond, at \$2.50 for 11-peck barrels, till sold out. 4-8

L. H. REDD, De Soto, Illinois.

The New Craig Seedling Potato.

For full description of this Potato, see page 959 of this journal for Dec. 15, 1894. Prices: 1 lb. by mail, postpaid, 25 cts.; ½ peck, by freight or express, \$1.00; peck, \$1.75; ¼ bushel, \$3.00; bushel, \$5.00; barrel of 11 pecks, \$12.50. The above prices will hold good as long as our stock lasts. All orders by mail will be filled as soon as received. Orders by express will be shipped at once unless ordered otherwise. All orders for potatoes by freight will be filled April 1, or soon after that time, unless directions are given to ship at an earlier date. In this latter case I do not assume responsibility for loss in freezing; but where it is desirable to ship earlier, and customers have bad luck, I expect to help them out so far as I can consistently. In regard to my responsibility I would refer you to A. I. Root. In fact, where it is more convenient you can order potatoes of the A. I. Root Co., instead of sending your orders to me.

Notes of Travel that were written for this issue were crowded out by a mass of other matter. They will appear in our next.

BEESWAX WANTED.

Since our last we have received a goodly number of good-sized shipments of beeswax; but we can, for the next two or three months, use all that our readers can send to us. We are paying now 29 cts. cash, 32 in trade, for average wax delivered here.

ALSIKE CLOVER SEED.

We have a good supply of choice seed, and it is plenty early enough to sow. There are many good reasons for sowing. Price of seed, \$2.00 per peck; \$3.80 per half-bushel; \$7.20 per bushel; \$14.00 for 2 bushels; 5 bushels or over, at \$6.60, bags included in each case.

CHOICE EXTRACTED HONEY WANTED.

We are in need of choice extracted basswood and clover honey. We prefer it in 60-lb. cans; but if we can not get it that way we will take it in some other way if we can buy it. Those who have a supply which they desire to sell, we shall be glad to hear from, with samples, stating quantity you have, how put up, and the price.

WHEELBARROWS AND LAWN-MOWERS REDUCED.

We call your attention to the adv't on the 3d cover page, and to the marked reduction in price, especially on lawn-mowers, which we have reduced one dollar each from the prices of last year. Surely at these low prices there are few in need of a mower who need remain without one. We still offer the same styles we have sold for several years.

PLANET JR. GARDEN IMPLEMENTS.

We are now supplied with this year's catalogs of Planet Jr. tools, which we shall be pleased to mail to those interested, together with our net-price sheet. We are making lower prices on these excellent tools than ever before, and there have been some valuable improvements added. Write for catalog, if interested in hand seed-drills, for all kinds of garden seeds, onion-sets, etc., hand or horse cultivators for all kinds of work in the garden.

CARLOAD SHIPMENTS.

Since our last report we have shipped the second car to Florida, to A. F. Brown, at San Mateo; a second car to F. A. Salisbury, Syracuse, N. Y.; a second carload to Wm. A. Selser, 10 Vine St., Philadelphia, Pa.; a carload of export orders through the port of New York, including about a third of a car for J. H. M. Cook, 78 Barclay St., New York. As we go to press we are loading a car for H. G. Acklin, St. Paul, Minn., which will be followed by one for G. G. Wickson, Los Angeles, Cal., and another to Barteldes & Co., Denver, Col.

MAPLE SUGAR AND SYRUP.

The weather so far has been very unfavorable to the production of the delicious sweets from the sugar maple, and the season is so far advanced that there can be at best but a light crop in this vicinity. Few will take the trouble to make sugar if they can get a market for syrup. Our orders for syrup are all filled, and we can supply many more at \$1.00 per gallon, in quantities, for choice syrup. We have booked a number of orders for sugar, but so far it has not been offered to us for sale by the producers, and we may be obliged to disappoint our friends; but we hope soon to be supplied; can offer no better prices than named in our last, and these only subject to our being able to get the sugar to furnish on orders we receive.

HIVE-MAKING MACHINERY.

If any one is interested in an outfit of machinery for hive-making we have a bargain to offer at Ottawa, Kan. The outfit consists of a 4 H. P. engine and boiler, a hive-dovetailing machine, a saw-table with a lot of grooving-saws and cutter-heads, a 10-

inch foundation-machine, and other tools. Cost new over \$600. Is in about as good condition as new, and can be bought for \$225 cash. Will send further particulars to those interested, on application.

WIRE NETTING AND FENCING CATALOGS.

We have for some time been short of wire-netting catalogs, but we are now supplied with a large new edition which we shall be pleased to mail those interested, on application. It includes a discount-sheet giving very low prices, and incorporates a page describing a new and very cheap sheep and hog fence. We are also prepared to furnish No. 12 smooth galvanized fence wire, 100-lb. bundles, at \$2.25 per 100 lbs., or barbed wire at \$2.75 per 100 lbs.

LABEL CATALOGS EXHAUSTED.

We regret to be obliged again to disappoint our friends who apply for label catalogs. Our store is exhausted, and our printers are now and have been so crowded with work that they have been unable to print a new edition. It is likely to be six weeks or two months before they will be able to complete an edition. We have a number of new designs in honey-labels, which will appear in the new catalog when ready, and we trust it will be ready in good time before the next honey-crop is taken. We will file all applications, and send catalogs as soon as ready.

SWEET-CLOVER SEED WANTED.

If you have any for sale, mail us a sample, tell us how much you have, and what you will take for it. By the way, it is really remarkable what a demand there is getting to be for sweet clover; and I for one should be very glad to know what people do with it. We are just now in receipt of an order for 350 lbs. Some time ago I used to feel troubled about large orders, for fear the friends did not know what they were ordering, and did not know what they wanted; but with the steady demand that is coming in now, there can hardly be a question but that it is being used as a fodder crop, or for something else besides these. Can anybody enlighten us?

OLD-STOCK SECTIONS.

We still have the following list of old-stock $4\frac{1}{4} \times 4\frac{1}{4}$ sections, made two, or three years ago, which we offer, to close out, at \$2.20 per 1000: 3000, \$6.00; 5000, \$9.00; 10,000, \$16.00.

109,000	$4\frac{1}{4} \times 4\frac{1}{4} \times 1\frac{1}{2}$	open top and bottom.
12,000	" "	open four sides.
9,000	" "	$x\frac{7}{8}$ to fl., closed top.
7,000	" "	open top and bottom.
8,000	" "	cream, or No. 2, new stock.
5,000	" "	$x1\frac{1}{4}$ closed top.
9,000	" "	open top and bottom.
3,000	" "	open four sides.
4,000	" "	$x1\frac{1}{8}$ closed top.
5,000	" "	open top and bottom.
10,000	" "	$x1\frac{1}{8}$ open 4 sides.
20,000	" "	$x2$, cream, open top, new stock.
20,000	" "	cream, open four sides.

At the very low price named above, these are a bargain. This is especially true of the $1\frac{1}{2}$ -inch sections, which are about equal to our extra polished as now made. If any one can use or handle a quantity of this width we shall be pleased to hear from them.

PARSNIP SEED AT A BARGAIN.

Last fall we succeeded in getting a tremendous crop, and the seed is all from the Improved Guernsey, nice large roots; but either we have not the proper machinery or else we do not understand the business of cleaning the seed. There are no seeds of weeds nor any thing of that sort, but there are little bits of stems and branches of the parsnip itself that can not be got out in any way we know of except by expensive hand-picking. These bits of stem no not, of course, hurt it in the least for sowing, but they make it look untidy; therefore we offer it at the following exceedingly low prices: 1 lb., 20 cts.; 5 lbs., 75 cts.; 10 lbs., \$1.25. Just now parsnips are selling in our market for 5 cts. per lb. Those that were dug and placed in the cellar last fall might have been sold at about the same price all through February and March if we had had enough of them. If you can not sell them all, horses, cows, pigs, and even chickens, are very fond of them. The above prices are to hold only so long as our stock holds out. The quicker you get them into the ground the better, after the frost is out, for parsnips will make quite a

growth before many kinds of weeds get up, if you give them a chance.

PRIZETAKER ONION SETS.

We have several bushels of these which we can furnish at 10 cts. per pint; 15 cts. per quart; \$1.00 per peck; \$3.50 per bushel. If wanted by mail, add 10 cts. per quart extra. Large sizes, half above prices.

LATHYRIS SYLVESTRIS AND SACALINE.

We have seed of both of the above in 5-cent packets, and can furnish sacaline-plants by mail postpaid for 20 cts. each. Plants of Lathyrus sylvestris, or flat pea, 5 cts. each; 25 cts. for 10, or \$1.50 per 100—postpaid by mail at above prices.

SEED POTATOES.

At present writing all our second-size potatoes are sold out. I think I must have made the price pretty low—half price right through. Well, I wanted some plan by which we could get rid of all small and otherwise objectionable tubers, so that we could give out for first-class only nice-looking, good-sized ones. We have so far all kinds of the No. 1 size, but several kinds are *nearly* sold out.

SPRAY-PUMPS AT REDUCED PRICES.

The time for spraying fruit-trees is near at hand; and those not already provided with a good spraying-apparatus, if they have the trees, and expect to get any choice fruit, should not fail to secure in time the necessary spraying-outfit. It is being demonstrated more surely every year, that it is absolutely necessary to spray fruit-trees of all kinds one or more times in order to secure a stand of reasonably perfect fruit. There are pests which attack the foliage as well as those which destroy the fruit. For the latter you should not apply the poisonous spray till the petals of the blossoms have all fallen off. Then there is no danger of poisoning the bees as they gather the nectar from the blossoms. To spray before the petals fall is worse than useless.

We are late in getting out our list of spray pumps this year. We call your attention to our line in the advertising pages. We do not believe you will get better value for the money anywhere than in the line we offer. To dealers, and those who buy to sell again, we will make special low prices in quantities on application.

The adjoining cut shows a pump which we secured after our other line was made up. This is very much like the Myers bucket pump. The rubber hose, $\frac{1}{4}$ inch, is attached to the top of a brass tube running up through the center of the air-chamber. This reduces the capacity of the air-chamber. The pump is lighter, and we do not think quite as good as the Myers; but for the price at which we offer it, \$2.50, it is a bargain. It can be sent by mail, postpaid, for \$3.25. An eight-foot pipe extension, not available, will be included at 35c extra.

OXYDONOR AND D. L. MOODY.

On the second page of the Oxydonor pamphlet, the Oxydonor people make use of the name of D. L. Moody as follows:

Our manager, Capt. R. Kelso Carter, is well known all over this country, and in England, to many thousands of the best people, as a college professor, a scientific and religious writer, and a prominent evangelist in Christian work, and as a lecturer of great ability and magnetism. As to his character, ask such men as Rev. A. J. Gordon, of Boston; Dwight L. Moody, and Major Cole.

I at once wrote to Mr. Moody, forwarding a leaf from their circular, containing the above paragraph. I also inquired of him whether it could be possible that he knew that his name was being used to push a fraud. His reply below comes to hand just as we go to press:

I know nothing about this, and never indorsed it. Chicago, March 26. D. L. MOODY.

"Magnetism" indeed! It must be this sort of magnetism that prompts them to use a good man's name in this way without permission.

WM. STAHL, Quincy, Ill.

Last year we commenced an elaborate plan of advertising, but before we were half through, OUR ADVERTISEMENTS DISAPPEARED. Why? Because we WERE OVERWHELMED WITH BUSINESS. There was but one thing to do: withdraw the advertising and devote every energy to filling the orders with which we were flooded. This we did, and handled with reasonable promptness a most unprecedented year's business.

WITH ENLARGED FACTORIES, INCREASED FACILITIES, AND TWENTY BRANCH HOUSES FROM WHICH TO DISPATCH OUR GOODS, WE CAN NOW CARE FOR ALL WHO COME. Last year we could not reduce prices because we were compelled in some way to limit the demand for Aermotor goods. We would have been satisfied with lower prices, but why create a demand which we could not supply? We have made the heaviest purchases of steel and material bought in America this year, and at unprecedented prices, and have made terms to dealers which enable them to make unprecedented prices.

In quality, character, variety, finish, and accessibility to full stock of goods and repairs, we are without competitors. In our plan of advertising last year, we proposed to furnish a feed cutter under certain conditions for \$15. For reasons stated above we did not complete the advertising, and the feed cutter is not put out. We now propose to make annuities in the following manner: We will announce in this paper our NEW ALL-STEEL VERY SUPERIOR FEED CUTTER, WORTH

\$40 at \$10

cash with order, f. o. b. Chicago. Only one to one person, he to furnish addresses of ten neighbors who ought to have something in our line. Cut, description and full information regarding it will appear soon.

We especially desire to caution you against paying excessive prices for windmills on the part of the dealer to overcharge the legitimate profit to the dealer. To be sure, the dealer will protect you, but we will protect you. We have been enabled to have special tools for each piece, and on it to merely to run down again. So small has become the cost of labor put sell that it is not worth come the largest dealers in the material, of course, he steel galvanized after coating (tilting and fixed), tanks, extent has this become true, the price of our goods (and of our business reputation) is so low that competition is impossible. **THEY DO IT BECAUSE THEY CAN BUY OF US CHEAPER THAN THEY CAN BUILD; BECAUSE WE ALONE ARE PREPARED TO GALVANIZE EVERYTHING AFTER IT IS COMPLETED, AND COMPLETE EVERYTHING EXACTLY RIGHT.**

These concerns are wise, for, even though we may not furnish the best of wheels, the wheel will have the best of supports. Send to us your name and address, and those of your neighbors who may need something in our line, and thereby do them a good turn. The Aermotor Co. is one of the most successful business enterprises which has been launched in recent times. In succeeding advertisements will be discussed and made clear the lines on which that success has been worked out. It was done by a farmer's boy. A careful following of these advertisements may suggest to some other farmer's boy a career.

LEAHY MFG. CO., HIGGSVILLE, Mo.

FACTS FROM THE FACTORY.

The Page is the only elastic fence made, and requires special wire. Our contracts for the manufacture of this wire cover many thousands of tons, all guaranteed to suit the purpose. The Superintendents of the largest mills in the country have spent days at our factory studying our particular needs. This wire costs more than the common article, which could not be used if furnished free. Our complete fence costs the farmer less than he can buy the wire of which it is made and is the cheapest in the end.

HONEY COLUMN

CITY MARKETS.

CHICAGO.—Honey.—We report our market well cleaned up on fancy white comb honey in 1-lb sections. A neat package and a fancy article would sell quickly at 14c. No. 2 comb, or dark, would not sell at over 10¢@11. We report better inquiry for extracted, at 5¢@7, depending on quality. Beeswax selling at 30c. S. T. FISH & CO.,
April 8. 189 South Water St., Chicago, Ill.

PHILADELPHIA.—Honey.—The supply of comb honey is getting low in this market, with considerable call; selling at 11¢@14, as to quality. Extracted honey in fair demand and good supply at 6¢@6½c. WM. A. SELSER,
April 9. 10 Vine St., Philadelphia, Pa.

BOSTON.—Honey.—Our market on No. 1 white comb honey is well cleaned up, and it is wanted. Prices for fancy 1-lb. white comb in cartons, 14¢@15c. E. E. BLAKE & CO.,
April 9. Boston, Mass.

KANSAS CITY.—Honey.—The stock of comb honey is large; market well supplied. Fancy white 1-lb. combs, 13¢; amber, 11¢. Receipts of extracted light; white, 7¢; amber, 5¢@6¢; Southern, 4¢@5¢. Beeswax, 22¢. HAMBLIN & BEARSS,
April 8. Kansas City, Mo.

KANSAS CITY.—Honey.—The supply of comb and extracted, fairly large. We quote No. 1 white 1-lb. comb, 14¢@15¢; No. 2, 12¢@13¢; No. 1 amber, 12¢@13¢; No. 2, 10¢@11¢; extracted, 5¢@7¢. Beeswax, 22¢@25¢. C. C. CLEMONS & CO.,
April 8. Kansas City, Mo.

BUFFALO.—Honey.—The honey market is cleaning up quite satisfactorily. Sales, however, are light. Fancy moderate at 13¢@14¢; choice, 11¢@12¢; commoner grades, ranging from 8¢@9¢; buckwheat very slow, and hard to sell at any satisfactory prices. BATTERSON & CO.,
April 9. Buffalo, N. Y.

DETROIT.—Honey.—Best white comb in light demand at 13¢@14¢; darker and inferior lots, 10¢@11¢. Extracted, 6¢@7¢, with few sales. Beeswax in better demand, and selling on sight at 29¢@30¢. M. H. HUNT,
April 8. Bell Branch, Mich.

CHICAGO.—Honey.—The market is well cleaned out at this writing, of all grades of comb honey excepting some lots of comb in cartons, which is not a popular way of marketing in this city. Best grades of comb sell at 14¢; dark, 8¢@10¢; yellow comb, 10¢@12¢. Extracted, 5¢@7¢, according to quality, flavor, and package. Beeswax chiefly at 30¢. R. A. BURNETT & CO.,
April 8. 163 So. Water St., Chicago, Ill.

CINCINNATI.—Honey.—There is a slow demand for all kinds of honey. We quote extracted honey at 4¢@7¢ on arrival. Comb honey, 12¢@16¢ in the jobbing way for best white. Dark honey is unsalable. Beeswax is scarce and in good demand at 25¢@28¢ for good to choice yellow. CHAS. F. MUTH & SON,
April 9. Cincinnati, O.

CLEVELAND.—Honey.—Our honey market is very slow at present. We quote No. 1 white, 1-lb. sections, 13c; No. 2, 11c. There is a better demand for extracted; No. 1, white, 7¢@8¢. Beeswax, 28¢@30¢. WILLIAMS BROS.,
April 8. 80 & 82 Broadway, Cleveland, O.

MILWAUKEE.—Honey.—This market for honey presents no new features since our last, and we are enjoying some trade both for comb and extracted. Our supply is fair, and the quality the very best. We quote finest 1-lb. sections, 15¢@16¢; good, 14¢@15¢; common, 12¢@13¢; mixed, 10¢@12¢. Extracted in barrels and kegs, white, 7¢@7½¢; dark, 6¢@6½¢; white in pails, 8¢@10¢. Beeswax wanted at 26¢@28¢. A. V. BISHOP & CO.,
April 8. Milwaukee, Wis.

ALBANY.—Honey.—Have received quite a number lots of comb honey during the past few days, and it has found a ready sale at a slight advance in price. We quote fancy white, 13c; mixed and buckwheat, 9¢@11¢. Extracted, 5¢@6½¢. CHAS. MCCULLOCH & CO.,
April 8. Albany, N. Y.

ALFALFA HONEY, very white, thick, and rich. Two 60-lb. cans at 7c. Same, partly from cloome (tinted), 6c. Samples, 8c. OLIVER FOSTER, Las Animas, Col.

BUFFALO, N. Y. Unsurpassed Honey Market. BATTERSON & CO. Responsible, Reliable, Commission Merchants. 18tfab and Prompt.

High=Grade Bicycles

ONLY \$60.00.

These are high-grade in every respect, both as to material and workmanship. We have personally tested them thoroughly, and know that they are first-class.

Tires, Morgan & Wright or Hartford single-tube pneumatic tires; wheels, 28-inch, wood rims; ball bearings throughout; pedals, rat-trap or rubber; handle-bars, raised or drop; frame of best quality of drawn seamless steel tubing; weight, 28 lbs. The entire bicycles are built by one of the largest bicycle works in the country. The extremely low price is owing to the fact that they are made on '94 machinery, and under another name-plate. We can furnish gentlemen's or Ladies' wheels at this price. Write for circular.

**THE A. I. ROOT COMPANY,
MEDINA, O.**

FOR SALE.—250 good Brood-combs.

Books for Bee-Keepers and others.

Any of these books on which postage is not given will be forwarded by mail, postpaid, on receipt of price.
In buying books, as every thing else, we are liable to disappointment if we make a purchase without seeing the article. Admitting that the bookseller could read all the books he offers, as he has them for sale, it were hardly to be expected he would be the one to mention all the faults, as well as good things about a book. I very much desire that those who favor me with their patronage shall not be disappointed, and therefore I am going to try to prevent it by mentioning all the faults, so far as I can, that the purchaser may know what he is getting. In the following list, books that I approve I have marked with a *; those I especially approve, **; those that are not up to times, †; books that contain but little matter for the price, large type, and much space between the lines; ‡; foreign; §. The bee-books are all good.

BIBLES, HYMN-BOOKS, AND OTHER GOOD BOOKS.

As many of the bee-books are sent with other goods by freight or express, incurring no postage, we give prices separately. You will notice, that you can judge of the size of the books very well by the amount required for postage on each.

8	Bible, good print, neatly bound.....	20
10	Bunyan's Pilgrim's Progress**.....	30
20	Illustrated Pilgrim's Progress**.....	75
This is a large book of 425 pages and 175 illustrations, and would usually be called a \$2.00 book. A splendid book to present to children. Sold in gilt edge for 50c more.		
6	First Steps for Little Feet. By the author of the Story of the Bible. A better book for young children can not be found in the whole round of literature, and at the same time there can hardly be found a more attractive book. Beautifully bound, and fully illustrated. Price 50 c. Two copies will be sold for 75 cents. Postage six cents each.	
5	Harmony of the Gospels.....	35
3	John Ploughman's Talks and Pictures, by Rev. C. H. Spurgeon*.....	10
1	Gospel Hymns, consolidated Nos. 1, 2, 3, and 4, words only, cloth, 10 c; paper.....	05
2	Same, board covers.....	20
5	Same, words and music, small type, board covers.....	45
10	Same, words and music, board covers.....	75
3	New Testament in pretty flexible covers... ..	05
5	New Testament, new version, paper covers... ..	10
5	Robinson Crusoe, paper cover.....	10
4	Stepping Heavenward**.....	18
15	Story of the Bible**.....	1 00
A large book of 700 pages, and 274 illustrations. Will be read by almost every child.		
5	The Christian's Secret of a Happy Life**....	25
8	Same in cloth binding.....	50
	The Life of Trust, by Geo. Muller**.....	1 25
1	Ten Nights in a Bar-Room, T. S. Arthur**....	05
5	Tobacco Manual**.....	45

This is a nice book that will be sure to be read, if left around where the boys get hold of it, and any boy that reads it will be pretty safe from the tobacco habit.

BOOKS ESPECIALLY FOR BEE-KEEPERS.

MISCELLANEOUS HAND-BOOKS.

5	An Egg-Farm, Stoddard**.....	45
	Amateur Photographer's Hand-book**.....	70
3	A B C of Potato Culture, Terry**.....	35
This is T. B. Terry's first and most masterly work. The book has had an enormous sale, and has been reprinted in foreign languages. When we are thoroughly conversant with friend Terry's system of raising potatoes, we shall be ready to handle almost any farm crop successfully. It has 48 pages and 22 illustrations.		

- 5 | A B C of Carp Culture, by Geo. Finley..... 35
 5 | A B C of Strawberry Culture**By T. B. Terry 35
 Probably the leading book of the world on strawberries.
 Barn Plans and Out-Buildings*..... 1 50
 Canary Birds. Paper..... 50
 2 | Celery for Profit, by T. Greiner*..... 25
 The first really full and complete book on celery culture, at a moderate price, that we have had. It is full of pictures and the whole thing is made so plain that a schoolboy ought to be able to grow paying crops at once, without any assistance except from the book.
 8 | Domestic Economy, by I. H. Mayer, M. D.* 60
 This book ought to save at least the money it costs, each year, in every household. It was written by a doctor, and one who has made the matter of domestic economy a life-study. The regular price of the book is \$1.00; but by taking a large lot of them we are enabled to make the price only 60 cts.
 Draining for Profit and Health, Warring..... 1 50
 10 | Fuller's Grape Culturist**..... 1 40
 Farming For Boys*..... 75
 This is one of Joseph Harris' happiest productions, and it seems to me that it ought to make farm-life fascinating to any boy who has any sort of taste for gardening.
 7 | Farm, Gardening, and Seed-Growing**..... 90
 This is by Francis Brill, the veteran seed-grower, and is the only book on gardening that I am aware of that tells how market-gardeners and seed-growers raise and harvest their crops. It has 166 pages.
 12 | Gardening for Pleasure, Henderson*..... 1 85
 While "Gardening for Profit" is written with a view of making gardening PAY, it touches a good deal on the pleasure part; and "Gardening for Pleasure" takes up this matter of beautifying your homes and improving your grounds without the special point in view of making money out of it. I think most of you will need this if you get "Gardening for Profit." This work has 404 pages and 203 illustrations.
 12 | Gardening for Profit..... 1 85
 The latest revision of Peter Henderson's celebrated work. Nothing that has ever before been put in print has done so much toward making market-gardening a science and a fascinating industry. Peter Henderson stands at the head, without question, although we have many other books on these rural employments. If you can get but one book, let it be the above. It has 376 pages and 138 cuts.
 Gardening for Young and Old, Harris**..... 1 25
 This is Joseph Harris' best and happiest effort. Although it goes over the same ground, occupied by Peter Henderson, it particularly emphasizes thorough cultivation of the soil in preparing the ground; and this matter of adapting it to young people as well as old is brought out in a most happy vein. If your children have any sort of fancy for gardening it will pay you to make them a present of this book. It has 187 pages and 46 engravings.
 10 | Garden and Farm Topics, Henderson*..... 75
 Gray's School and Field Book of Botany..... 1 80
 5 | Gregory on Cabbages; paper*..... 25
 5 | Gregory on Squashes; paper*..... 25
 5 | Gregory on Onions; paper*..... 25
 The above three books, by our friend Gregory, are all valuable. The book on squashes especially is good reading for almost anybody, whether they raise squashes or not. It strikes at the very foundation of success in almost any kind of business.
 10 | Greenhouse Construction**..... 1 40
 This book, by Prof. Taft, is just out, and is as full and complete as regard to the subject of greenhouse construction. The next book in regard to their management. Any one who builds even a small structure for plant-growing under glass will save the value of the book by reading it carefully.
 15 | How to Make the Garden Pay**..... 1 35
 By T. Greiner. This is a new book, just out, and it gives the most full directions of actually making money out of any book in the world. Those who are interested in hot-beds, cold-frames, cold-greenhouses, hot-houses or glass structures of any kind for the growth of plants, can not afford to be without the book.
 Handbook for Lumbermen..... 10
 10 | Household Conveniences..... 1 40
 2 | How to Propagate and Grow Fruit, Green* 15
 2 | Injurious Insects, Cook..... 25
 10 | Irrigation for the Farm, Garden, and Orchard, Stewart*..... 1 40
 This book, so far as I am informed, is almost the only work on this subject that is attracting so much interest, especially recently. Using water from springs, brooks, or windmills, to take the place of rain, during our great droughts, is the great problem before us at the present day. The book has 274 pages and 142 cuts.
 5 | Manures; How to Make and How to Use them; in paper covers..... 45
 6 | The same in cloth covers..... 65
 Covering the whole matter, and discussing in detail to be found on the farm, refuse from factories, mineral fertilizers from mines, etc. It is a complete summing-up of the whole matter. It is written by F. W. Semper.
 7 | Market-gardening and Farm Notes, by Burnett Landreth..... 90
 The Landreths are the pioneer seedsmen of America; and the book is worth fully as much as we might expect it to be. I think from the fact that it was the price, before it had been in my hands fifteen minutes. It is exceedingly practical, and tells what has been done and what is BEING done, more than it discourses on theory.
 3 | Maple Sugar and the Sugar-bush**..... 35
 By Prof. A. J. Cook. This was written in the spring of 1887 at my request. As the author has, perhaps, the largest maple-sugar-camps in the United States, as well as being an enthusiastic lover of all farm industries, he is better fitted, perhaps, to handle the subject than any other man. The book is written

in Prof. Cook's happy style combining wholesome moral lessons with the latest and best method of managing to get the finest syrup and maple sugar, with the least possible expenditure of cash and labor. Everybody who makes sugar or molasses wants the sugar-book. It has 42 pages and 35 cuts.

Our Farming, by T. B. Terry**..... \$2.00
 In which he tells "how we have made a run-down farm bring both profit and pleasure."

This is a large book, 6x9 inches, 367 pages, quite fully illustrated. It is Terry's first large book; and while it touches on the topics treated in his smaller handbooks, it is sufficiently different so that no one will complain of repetition, even if he has read all of Terry's little books. I should call it the brightest and most practical book on farming before the world at the present day. The price is \$2.00 postpaid; or, clubbed with GLEANINGS for \$2.50. Those who are already subscribers to GLEANINGS may have it postpaid by sending us 1.50 more. We are so sure it will be worth many times its cost that we are not afraid to offer to take it back if any one feels he has not got his money's worth after he has read it. If ordered by express or freight with other goods, free less.

3 | Onions for Profit**..... 45
 Fully up to the times, and includes both the old onion culture and the new method. The book is fully illustrated, and written with all the enthusiasm and interest that characterizes its author, T. Greiner. Even if one is not particularly interested in the business, almost any person who picks up Greiner's books will like to read them through.

1 | Poultry for Pleasure and Profit**..... 10
 11 | Practical Floriculture, Henderson*..... 1 35
 10 | Profits in Poultry*..... 90
 2 | Practical Turkey-raising..... 10
 By Fanny Field. This is a 35-cent book which we offer for 10 cts.; postage, 2 cts.

4 | Peabody's Webster's Dictionary..... 10
 Over 30,000 words and 250 illustrations.

2 | Rats: How to Rid Farms and Buildings of them, as well as other Pests of like Character..... 15

This little book ought to be worth dollars instead of the few cents it costs to any one who has ever been troubled with these pests, and who does not. It is written in such a happy vein that every member of the family will read it clear through, just about as soon as they get hold of it. It contains a complete summing up of the best information the world can furnish.

1 | Silk and the Silkworm..... 10
 10 | Small-Fruit Culturist, Fuller..... 1 40
 10 | Success in Market-Gardening*..... 90
 This is a new book by a real, live, enterprising, successful market-gardener who lives in Arlington, Mass., of Boston, Mass. Friend Rawson has been one of the foremost to make irrigation a practical success, and he now irrigates his grounds by means of a windmill and steam-engine whenever a drought threatens to injure the crops. The book has 208 pages, and is nicely illustrated with 110 engravings.

10 | Ten Acres Enough..... 1 00
 Talks on Manures*..... 1 75

This book, by Joseph Harris is, perhaps, the most comprehensive one we have on the subject, and the whole matter is considered by an able writer. It contains 366 pages.

2 | The Carpenter's Steel Square and its Uses..... 15
 10 | The New Agriculture; or, the Waters Led Captive..... 75
 2 | Treatise on the Horse and his Diseases..... 10
 5 | Tile Drainage, by W. I. Chamberlain..... 35
 Fully illustrated, containing every thing of importance clear up to the present date.

The single chapter on digging ditches, with the illustrations given by Prof. Chamberlain, should alone make the book worth while. It costs, to every one who has occasion to lay ten rods or more of tile. There is as much science as in doing almost anything else; and by following the plan directed in this book, one man will often do as much as two men without this knowledge. The book embraces every thing connected with the subject, and was written by the author while he was engaged in the work of digging the ditches and laying the tiles HIMSELF, for he has laid literally miles of tile on his own farm in Hudson, O.

5 | Tomato Culture..... 35
 In three parts. Part first—by J. W. Day, of Crystal Springs, Miss., treats of tomato culture in the South, with some remarks by A. I. Root, adapting it to the North. Part second—By D. C. Corbin, of Connecticut, treats of tomato culture especially for canning factories. Part third—By A. I. Root, treats of plant-growing for market, and high-pressure gardening in general. This little book is interesting because it is one of the first rural books to come from our friends in the South. It tells of a great new industry that has been steadily growing for some years past; namely, tomato-growing, the South to supply the Northern markets. The little book, which is fully illustrated, gives us some pleasant glimpses of the possibilities and probabilities of the future of Southern agriculture. Even though you do not grow tomatoes to any considerable extent, you will find the book brimful of suggestions and short cuts in agriculture and horticulture, and especially in the line of market-gardening.

3 | Winter Care of Horses and Cattle..... 35
 This is friend Terry's second book in regard to farm matters; but it is so intimately connected with his potato-book that it reads almost like a sequel to it. If you have only a horse or a cow, I think it will pay you to invest in the book. It has 44 pages and 4 cuts.

3 | Wood's Common Objects of the Microscope**..... 47
 8 | What to Do and How to be Happy While Doing It, by A. I. Root..... 50

THE A. I. ROOT CO., MEDINA, O.

TESTED QUEENS

Are usually sold for \$2.00. I will explain why I wish to sell a few at less than that. As most of my readers know, I require my apiary each spring with young queens from the South. This is done to do away with swarming. If done early enough it is usually successful. It will be seen that the queens displaced by these young queens are never more than a year old; in fact, they are fine, tested, Italian queens, RIGHT IN THEIR PRIME; yet, in order that they may move off quickly, and thus make room for the untested queens, they will be sold for only **ONE DOLLAR**. Or I will send the REVIEW for 1895 and one of these queens for only \$1.75. For \$2.00 I will send the REVIEW, the queen, and the book "Advanced Bee Culture." If any prefer the young, laying queens from the South, they can have them instead of the tested queens, at the same price. A discount on large orders for untested queens. Say how many are wanted, and a price will be made. Orders can be filled as soon as it is warm enough to handle bees and ship queens with safety.

W. Z. HUTCHINSON, Flint, Mich.

Established in 1861.

A JOURNAL DEVOTED TO BEES AND HONEY AND HOME INTERESTS ILLUSTRATED SEMI-MONTHLY Published by THE A. B. J. CO. MEDINA, OHIO. \$1.00 PER YEAR

Vol. XXIII.

APR. 15, 1895.

No. 8.

STRAY STRAWS FROM DR. C. C. MILLER.

FIVE CENTS is enough to invest in sacaline till more is known about it.

SLICED ONIONS are given to bees 24 hours before uniting, by Wm. Stolley.—*A. B. J.*

F. L. THOMPSON has been doing some good work culling from foreign journals for *Review*.

GLEANINGS is troubled to know what's done with so much sweet clover. M. M. Baldrige says some of it is used for tanning.

CHAFF HIVES are the things for East Tennessee, with its ever-changing warm and cold spells in winter, according to Adrian Getaz in *A. B. J.*

A CRUSADE ought to be started against respectable papers—at least respectable in other respects—for advertising such frauds as Electropoise.

THAT MAN BOARDMAN must be squelched. He's trying to break in on established traditions and customs, getting us to hanker after old straw skeps and square frames.

I'M GLAD the big-little-hive discussion is not to be closed yet. Not that a positive decision is sure to be reached, but incidentally the discussion brings out points of value.

THE WISCONSIN CONVENTION seemed to think the "expert and careful bee-keeper" could get along without separators. Don't you think he'd get along just a *little* better with them?

MRS. EDITH MILLER is the name that stands at the mast-head as editor of the new paper, *The Kansas Bee Journal*. If Mrs. Edith is a genuine live bee-woman, that paper ought to succeed.

BROOD-SPREADING seems to be taking a back seat. Of 23 repliers in *A. B. J.*, only one indorses it unqualifiedly. Doolittle and a few others use it less than formerly, and the majority will none of it.

LARGE-HIVE advocates are appearing in *A. B. J.* Adrian Getaz says, "Eight hives of thir-

teen frames each will probably give more surplus, and certainly as much, as thirteen hives of eight frames each."

DO BEES WORK on strawberry-blossoms? Abbott says, in *A. B. J.*, that Secor's wrong in thinking they don't. I don't remember ever seeing them at it, and I've had strawberries by the acre; but that isn't proof positive.

"I PLACED in a long trough, in separate piles, wheat flour, wheat Graham, rye flour, rye Graham, ground oats, oat-meal, buckwheat flour, and corn meal, and found the bees would hardly touch any thing else till the cornmeal was all gone."—O. K. Omstead, in *A. B. J.*

"NO DANGER of the swarm absconding or doubling up with others as long as you trap all the queens," says C. H. Dibbern, p. 258. But I'm sorry to say swarms sometimes return to the wrong hive, which is the same as doubling up.

THE *Australian Bee Bulletin* says, at the last of January, "Swarming may now be said to be practically over." I should think so! That accounts for the big crops they get there. We could get big crops too if we would work the poor bees right through the winter.

THE PAST WINTER has been a terror across the sea. In England the mercury went down to 8° below zero; and one man says in *B. B. J.*, "If a recurrence of this extreme weather takes place, we should make some experiments on the American plan of cellar wintering."

ALFALFA IN WISCONSIN. A report of a third of an acre is given by S. Favil, in *Prairie Farmer*. First year it didn't show much; second year gave two good cuttings, and four cuttings the third year. Flourishes in drouth that checks red clover, and doesn't need re-seeding.

FOUNDATION made of two-thirds ceresin, we are told on p. 272, is sold in Germany *for what it is*. I'm afraid there's some mistake about that. There's much complaint in the German journals about adulteration, but I never saw a word in favor of the mixed article, nor any of it offered for sale.

CLOVER SEED. Waldo F. Brown says, in *Prairie Farmer*, "In my experience the mammoth clover will in good seasons average about

one bushel of seed more to the acre than the medium; and from reports at institutes the past winter, the alsike will give nearly double the yield of the red clover.

ADULTERATED HONEY from America, according to one writer in *Centralblatt*, floods the German markets to the extent of 5,500,000 pounds. On another page of the same journal, H. Guehler, the C. F. Muth of Berlin, asserts that there is probably very little adulterated American honey, what is adulterated being generally done by Germans in Germany.

HASTY says in *Review* that he believes the leading thinkers no longer hold to the old theory that the queen at impregnation receives into her spermatheca a supply of spermatozoa that lasts for life. Don't you be fooled by noise, Hasty. That battle is being mostly fought in Germany, and the bulk of the leading thinkers hold to the old theory.

CATCHING SWARMS. Here's how it's done in Florida. A box 14x8x4 inches placed on the end of a long pole, placing in it a queen with a handful of bees and hanging it out every day during the swarming season. Clipping the queens' wings throughout the apiary, the bees in coming out to swarm will cluster around this box, sometimes 7 or 8 swarms together, and are hived as one swarm.—A. B. J.

BEE PARALYSIS. Joshua Bull, in *Review*, says he failed to cure a very bad case with salt brine, then made a success in this way: "I took a large spoonful of salt, and dissolved it in a little water, just enough to get the salt all dissolved, and mixed this with a gallon of honey and fed it to them just as fast as I could get them to take it." That cured for good. Now the question is, whether it will work the same with a bad case down south.

THE LANGSTROTH VS. THE CUBICAL HIVE.

THE QUESTION CAREFULLY CONSIDERED BY AN
ADVOCATE OF THE LATTER; A VALUABLE
AND READABLE ARTICLE.

By H. R. Boardman.

The lifting and carrying of hives in and about the bee-yard in the hot and busy part of the season, when the hives are stored with honey, is certainly an important item of the hardest, most trying work of the apiary. Then the carrying in and out of winter quarters, where bees are wintered indoors, all suggests, in a forcible manner, the convenience of hives for such manipulation.

The square hive is most perfectly adapted to this purpose. I could suggest no improvement in that respect. When lifted by the cleats it

makes a well-balanced load, and is easily carried. In this respect the least that can be said of the long hive is that its construction suggests little thought of convenience.

I have seen two men tugging away at a Simplicity hive, to carry it into winter quarters, when either of them would be able to pick up a square hive of the same weight, and carry it in quicker and easier.

In these times of sharp competition and short honey crops it is the sum total of these little items that sometimes tips the balance toward the side of success or failure in bee-keeping. It is only along the lines of strictest economy that we can now hope for success.

The queen insists on a round, compact brood-nest, when unrestricted. In carrying out this natural instinct in the long shallow hive, the brood nest is necessarily carried into the surplus-chamber. In order to correct this fault (?) perforated-zinc queen-excluders and other expensive devices are used to keep the queen out of the surplus-chamber. The trade in perforated zinc for this purpose has become an important item. That this is wholly a fault of the hive, it is only necessary to say that, with the square hive, this fault does not appear. The queen never goes into the sections unless by some mistake or awkwardness of management. The brood-chamber furnishes just the natural requirements for a brood-nest.

A few years ago I was one day in the apiary of a friend who used the Simplicity hive. He had been at work taking off sections. "My bees are very cross," said he. "I am having a disagreeable muss. The frames in my hives, in the upper and lower stories, are built solid together; and when I lift off the section-chamber it pulls up the brood-combs from the lower hive. I am getting a little disgusted with the way it works. How do you manage this trouble?"

"I never had any such experience," said I. "Let me see your hives."

We lifted the cover from a hive that had just had the sections removed. I did not wonder that my friend had become disgusted. There was enough to disgust any order-loving bee-keeper. The long top-bars had sagged until the bee-space over some of them was at least an inch, others were less, while some were nearly straight. All of these spaces, of course, had been filled with irregular masses of comb and propolis, and were stored with honey.

"I do not need to tell you that all this trouble is the fault of your hive. Look at those thin top-bars. Their strength is out of all proportion to their length, and the weight they have to support. I think the remedy for this trouble is a properly constructed hive."

"I guess you are nearly right," said he, "and if this accumulation of old traps were all off my hands I would improve upon your suggestion as well as my own past experience, and

I will assure you that I would make some very radical changes in starting again.

To mend these faults, honey-boards of various kinds have been introduced. The bracing and strengthening of the frames in various ways to prevent sagging was resorted to, and finally the thick top-bar came to cure a multitude of evils. It certainly is gratifying to note that this improvement is at least a safer extreme than the other.

It is claimed, as a valuable feature of the long hive, that it furnishes a large amount of surplus room close to the brood-nest. I think it remains to be shown that this is a valuable feature; that there is any advantage in such an arrangement. I am quite sure that this is also a mistaken economy.

CLUSTERS IN SQUARE AND LONG HIVE.

A considerable degree of heat is necessary in order to carry on comb-building. How to conserve and economize this heat in the surplus-chamber to the best advantage is an important question; and especially when the nights are cool, it sometimes becomes difficult and perplexing. The best and most satisfactory work in the sections can always be obtained directly over the brood-nest, and in a central compact form tiered up to the capacity desired. Being placed directly over the heat-center, it best conserves and economizes the accumulated heat from the brood-nest within; and, being in a rather compact form, protects from needless surface exposure without. In the square hive the sections are thus tiered up in a compact form over a compact brood-nest. Now if, instead of being thus tiered up, these sections

were disposed in one tier to adjust them to the long hive, so that a greater number would come next to the top of the brood-combs, would it need much argument to demonstrate that we have spread out, or dispersed, the heat over more surface, and at the same time placed a part of the sections farther from the heat-center? We have also increased the outside surface exposure to a considerable extent. I am quite sure that the second or third tier of sections on the square hive is in a more favorable position for good work than are the outside sections on the long hive. What is the testimony of the bees themselves? Have your bees got nicely at work in the sections? Go out into the yard and examine a few cases, and see where they commence their work and how they

continue it. This is what I think you will find, if you have the long hive: Work beginning centrally in the cases, and extending toward the outside, finishing in the central part, may be, before work is much advanced in the extreme outside. If a second case is on, work begun centrally, and well advanced, before the outside of the lower tier is finished—if you do find this, it will, no doubt, suggest to you that the central portion is the preferred part of the case for work.

There is one argument yet unanswered, that stands upon the side of the long hive. It is one which presents a barrier more potent for opposition in the human mind than all the other arguments that reason can array. It is popular; it is in general use. The beginner inquires, "What hive shall I use?" He is recommended the one in general use, and the question is settled. Any other hive would have been as readily accepted. By far the larger part of the trade in hives has been, and is now, with a class of

bee-keepers who know nothing at all of the requirements of a bee-hive. Having once adopted any style of hive, it is by no means an easy matter to make a change to some other kind, nor is it advisable to do so without some very good reasons. Every bee-keeper knows how important it is to start right; but the question after all is, how to be sure we are getting that right start.

A tight or fixed bottom to a bee-hive is a feature that I have never been able to appreciate. Its economy or use I have never been able to comprehend. A great deal of my valuable manipulation of hives depends upon the open bottom. The tiering-up feature, perhaps, is the most important, but is not all, by any means. Examination from the bottom, without opening the hive, has for me some decided advantages.

In the spring I wish to keep in touch with my bees, and know at all times their exact condition. To examine them I pass rapidly along on the back side of the hives, weighing each one with delicate scales which I have in the ends of my fingers, and at the same time I tip the hive up and count the spaces between the combs in which there are bees. I have learned to do this work very rapidly; 30 minutes is sufficient time to go over 150 colonies. When I wished to examine the combs briefly, to locate the queenless colonies that may be in the yard, or for any other purpose, I tip the hives in such a manner that the sun will shine straight in at the bottom. With a few puffs of smoke I drive the bees from between the combs to be examined; then by pulling them slightly apart I have a good view clear to the top of the hive. This has the advantage of being quick and easy, and can be carried on at any time without attracting robbers; and in early spring you can take a look at the brood-nest without exposing it to the cold. The open-bottom hive is, in my mind, intimately connected with the solution of the winter problem. My hives have been carried in and out of winter quarters for years, without bottoms; others report that they are not able to make it a success. I was puzzled at first, and thought it was because they did not know how; but I suspect it is the exposure of the large open bottom of the long hive that causes disturbance of the bees. Now, may be this is also the key to the origin of this feature.

East Townsend, Ohio.

[You say there is one argument yet unanswered that stands upon the side of the long hive. Aye, there's the rub. It is the standard. It is adopted in the United States and Canada, in many of the islands of the sea, in New Zealand, and also in Australia. We may admit all your arguments in favor of the cubical hive; but what are we going to do about it? The situation, it seems to me, finds a partial parallel in this: Our present system of spelling is outrageous. All schoolchildren have to waste years over something that might be much better spent upon some other department of learning. Printers have to waste tons and tons of type for useless silent letters; and they have to waste years of time in setting them up and in throwing them down again. Pressmen have to waste press room, to say nothing of valuable space on the pages of our books and journals, and all for what reason? Because we are helpless, and can not change. Our books for centuries have been printed so as to accord essentially with our present methods of spelling.

The Langstroth system is adopted throughout the United States and a large part of the world; but, unlike the spelling of our language, it is not outrageous. By many it is considered unique. We have for years made our hives so that the earliest frames we ever made will fit the hives of our present manufacture, and *vice versa*.

There is one point that it seems to me you have not considered in speaking of the advantages of the cubical hive. It requires wider lumber, or else boards of one or more pieces matched together, because the hive is tall or deep; and the fewer cracks we can have in the side of a bee-hive, the better. The long hive

takes narrow barn-boards—lumber comparatively cheap in price; and a side or end of such a hive can be made of a whole board. It is true, *your* hive may be; but when you go beyond ten or twelve inches with the boards, you have got to pay more than *pro rata* price for the extra width. It appears, therefore, that the Langstroth hive is the cheaper of the two; and it is, therefore, cheaper to the bee-keeper.

There is one other point that has not, perhaps, been considered, and that is this: Bee-keepers who use the long hive seem to produce as much honey as those who use the cubical; at least, in all my readings (and I am forced necessarily to read a good deal on the subject of bees, both published and unpublished manuscript) I have never run across a case that I remember, where the square or cubical hive had the advantage in *net results* of comb or extracted honey produced.

There was a time when we had deep hives; and the experience of my father as well as my own seemed to be that the Langstroth frame was more easily manipulated and withdrawn from the hive. In your case you overcome the disadvantage somewhat by the use of the side-opening hive; but these are used but little, comparatively, if I am correct; and, besides, it is not possible to make such a hive as tight as one that has permanent sides and ends all around.

As to your last sentence, about the bees flying out from the bottom of the shallow hive, preparatory to putting them into the cellar, I believe you are entirely correct. I came to that conclusion myself after seeing you handle your hives, and trying the same in our own Langstroth.

It is not my purpose to make an attempt to overthrow your arguments, but only to give our readers an opportunity to see the question on both sides. You have fairly presented many of the arguments in favor of the long hive, and I only wished to add a few more that perhaps you have overlooked.—Ed.]

MANUM IN THE APIARY.

EARLY SPRING MANAGEMENT OF BEES; HOW TO LOOK OVER COLONIES WITHOUT WASTING TIME UNNECESSARILY, OR EXPOSING BEES TO COLD AIR.

By A. E. Manum.

"Good-morning, Leslie. Are you out taking a sun-bath this fine morning?"

"I have come over to get a setting of eggs. I want to try your new breed of fowls."

"Well, just go into the house, and my wife will put them up for you. I want to show this man where to put his horse."

"Manum, who is that chap?"

"His name is Abe Jones. He came here last week to see if I would allow him to work with me one day each week, during the bee season, and show him what I could in the management of bees, as I now manage them, and I consented to do so. He has a few bees."

"Well, that is a new kink in the business. It's a grand chance for him. He can care for his own bees, and at the same time take lessons of you. Does he pay you any thing for it?"

"Yes, he pays for his dinner, and for hay for his horse; in other words, he offered me \$10.00 for the season."

"Well, Mr. Jones, I suppose you are here for business; so we will get our smokers and go for the bees."

"Yes, Manum, I want you to put me through while I am here. I am not afraid of bees or work."

"Now, Jones, it is early in the season; and I want to say to you *now* that a colony of bees must not be kept long exposed to the cold air. We simply need to open the hives, and quickly look in to see if we can assist the bees in any way. In the first place, we will go through the yard, and open all the entrances to their full size by pulling out the slides. It being a warm spring day, and bees are flying nicely, this will give them a chance to clean house; and when we get through work, we will return the slides, because they require but a small entrance through April and the first half of May."

"Won't there a great many bees get lost or die on the snow?"

"No doubt a few of the old bees will never return to their hive; but that we can not help; however, it is so warm to-day there will be but few lost. If there were much wind, or if the air were chilly, I would not open a hive. You would, therefore, lose your journey this time."

"We will open this hive, No. 1, and take them by course. First, raise the cap very carefully, so as not to disturb the bees. Now remove the cushion, and next the ventilator and honey-board. I puff a little smoke to drive the bees down. It seems too bad, they are so very quiet. There—you can see now; they have a plenty of sealed honey; another puff of smoke, and now we see a small patch of capped brood. This colony is all right. They have a laying queen, plenty of honey, and are strong in bees. Now, Jones, as you were timing me, how long did I have this colony exposed?"

"I am surprised when I tell you that the hive was open only 41 seconds. Now, it would have taken me at least five minutes to satisfy myself of the condition of the colony; and if I learn no more to-day, I shall feel well paid for this day."

"Here we are to the 23d hive, and all have so far been nearly alike as to condition; but here we have a change. This colony is light, and short of honey. I will cover the bees at once with the cushion, and go to the honey-room for a comb of honey. I break the cappings, that the bees may get at the honey more readily. Now I will place it near the cluster, so the bees will have it near by, where they can keep it warm. I must take out a comb here from the cluster, to see if there are any eggs, as I see no capped brood. Yes, there are eggs; they are all right. Now I will cover them with this old meal-bag, and over it put the honey-board and cushion. This is to keep them as warm as possible. If I can keep them along until May, I can then assist them with brood and young bees from a strong colony."

"Why not give them brood now, and have the benefit of it sooner?"

"Because they are not strong enough to properly care for it; and, furthermore, it would be bad policy to take brood from any colony this early in the season. It would damage a strong colony more than it would help a light one. In fact, it would be no great help to the light one; better by far leave the brood in the strong colony to hatch, and then give the light one a few of the young hatched bees. You must remember that it is only the first week in April, and we are liable to have several days of winter weather yet. My experience teaches me that, the less I do with the bees thus early, the better for them. Here is No. 28, with a mouse-nest in it, and two of the outside combs badly mutilated. Close the entrance at once: I will try to kill the mice with this new ventilator. Here is a new use for my ventilator. It is just the thing to punch the mice with. There! there! and there! I guess, that is all there are—three of them. Now I will remove the nest, and put in two combs partly filled with honey, as I see this colony has not an overabundance, and they are quite strong in bees."

"Oh, my! this 29th colony is dead."

"No, there are a few bees away down in that corner. I will remove a comb and examine. There is the queen—a nice one too. I will set the comb back, cover the hive, and get a partially filled section. I usually save out a few for this purpose. There! this section, you see, has wood sides, making a box of it. I'll now put 40 or 50 bees with the queen into this box, and break up the colony entirely. I can in this way keep the queen several days by keeping the box in a warm room in the house. Now, when I come to look over the remainder of my bees, which I hope to do this week, I may find a queenless colony. If I should, this queen will come handy. Next week, the work will be a little different. Be sure to choose a still, warm day, or you may lose your journey."

Bristol, Vt.

[I take it from the foregoing that Mr. Manum is going to give us a series of practical articles especially designed for beginners, so that not only Abe Jones, but a large number of Abe Joneses, will have the benefit of tutor Manum's instruction. As Mr. Manum makes his bees pay, I have no doubt that many of the veterans can glean here and there a fact worth much to them. Yes, Mr. M., I hope you will give us a full report of your instructions to Abe, and give him a hearty hand shake for me.—ED.]

SEPARATORS.

A READABLE AND PRACTICAL ARTICLE FROM
A PRACTICAL BEE-KEEPER.

By N. D. West.

I notice on page 210, B. Taylor would have us fall in line with him—make our sections narrow, and cleat our separators, and all this and that.

Why, Mr. Taylor, we can't, *can't* do it. We ought not to do it. Why, sir, if we should change our sections every year or two, we should not get anywhere. We take only one step ahead, and then we only step over in a side rut in the road, when we change; no better, but we get another rut in our road, and it costs something to change. Now, sir, it does not matter so much what kind of sections we use, if all would use one kind, so that a box of honey would be a box of honey, just as much as a barrel of flour is a barrel of flour. So far as the size is concerned, it would be far better for the supply-dealers, better for the producers, better for all who have anything to do with the honey crop, if we could have a uniform section and shipping-crate. How many poor widows have had to sell their bees at less than half their value because their husbands had kept changing their hives, their sections, etc., from time to time, until their barn, shop, and every store-room on the place was filled with all kinds of bee-rubbish, good for nothing! The poor widow can't run the bees, and has to sell them at auction in about 14 kinds of hives, together with the rubbish, to the highest bidder at about the price of kindling-wood. If everybody would make his hives and sections alike, we could buy and sell bees at any time for their value; but we are not all alike, and so we must differ from other folks.

The $4\frac{1}{4} \times 4\frac{1}{4} \times 1\frac{1}{8}$ is the section that I am using, and I like it best of all. First, $4\frac{1}{4} \times 4\frac{1}{4}$, because more use this size than any other. Second, I want them $1\frac{1}{8}$ wide because that width suits me best, all things considered. I am producing honey for the money there is in it, and I can as yet get more clean money from my bees by using a section $4\frac{1}{4} \times 4\frac{1}{4} \times 1\frac{1}{8}$ than I can by using a section $4\frac{1}{4} \times 4\frac{1}{4} \times 1\frac{1}{4}$. I have had a little experience with these two widths. A commission merchant told me that my honey would bring more in the narrow section, which weighs from 10 to 12 ounces, or one pound with glass on. Two years ago I used 6000 of these $1\frac{1}{8}$ sections, and about 16,000 of the $1\frac{1}{4}$ section, and last season I used up about 2000 of the $1\frac{1}{8}$ sections that I had left, and I gave them a fair test, and the $1\frac{1}{8}$ -wide section was decidedly the more profitable section for me. I wish I had the figures to give exact, but I can't now find the paper that I kept the account on. But I figured it as closely as possible.

To begin with, I will say that I can use one kind of section as well as the other on the hives, as 14 sections $1\frac{1}{8}$ wide fill one of my half-clamps, including separators and follower; and 16 sections $1\frac{1}{4}$ wide fill the same clamp, including separators and follower, and two clamps cover one hive; sections run the same way the brood-frames do on this kind of hive; and, again, I have 200 swarms in smaller hives, the clamps of which hold 21 of the $1\frac{1}{8}$ sections, and 24 sections $1\frac{1}{4}$ wide; and on these hives the sec-

tions run across the brood-frames. Now, Mr. Editor, I figured from 100 colonies in this way: Say 100 colonies fill four clamps of honey each (I will not give all the figures now, as they are laid aside). I could not get any more clamps filled of one kind than of the other, but the best work was done in the clamps with wide sections. But the 3200 sections $1\frac{1}{8}$ wide did not weigh as much as did the 2400 sections $1\frac{1}{4}$ wide. But in using the $1\frac{1}{8}$ section I had 800 sections more to pay for; also the extra foundation to fill them, besides all of the time needed to handle them. This I do remember: that, if I sold the honey in the $1\frac{1}{8}$ section from the 100 swarms for 10 cents per pound, I should have more money than by using the $1\frac{1}{4}$ section, and selling the honey at 11 cents per pound. Both were sold at the same price.

My shipping-crates hold 24 of the $1\frac{1}{8}$ sections, and the same crate will hold 28 of the $1\frac{1}{4}$ sections, but the latter does not weigh as much per crate, so the cost is more to buy crates for the narrow section.

Again, the comb in the narrow sections is more liable to be attached to the separators than are the wide ones, from this fact: If a hive does not stand level, so that the foundation in the narrow box can swing but a trifle, it will cause the bees to attach the comb to the separators more or less.

Mr. Taylor says that, long ago, he discovered the great value of drawn empty combs in sections for getting a large yield of white comb honey; and he found, too, that, by using them, he wanted separators. I am glad of it. So do I; but I don't want the kind he uses.

□ I was going to say more about separators when I commenced, but will not now. But I will say a word about what I have noticed with drawn comb in the sections. I prize them very much, and use one row (the center one) in every clamp that I put on my hives before I tier up. Here, again, the narrow sections are more liable to be occupied with brood than wide ones. I will admit that the section 5 inches high has an advantage over a lower section of the same weight.

Middleburg, N. Y.

[On my first bicycle-tour I called at the home of N. D. West, in 1890. The gentleman himself was absent, but I was kindly shown about by his son. I saw evidences enough to convince me that Mr. West was one of the bright, intelligent bee-keepers of York State. I afterward learned that he was a successful manager of some 300 or 400 colonies distributed in one or more out-yards. I had the pleasure of making his acquaintance at one or more of the York State bee-conventions. At the meetings which I attended he was full of ideas, and was ready to give them to his brother-workers. The article is a fairly good sample of what he knows about bees; and the arguments he presents seem to be almost incontrovertible, not the least important of which is the idea of having regular goods—something that everybody can use, and which have a par value among bee-keepers everywhere. —Ed.]

RAMBLE NO. 130.

AT ST. HELENA.

By Rambler.

UR Spanish neighbors had regained their equilibrium in the morning; and as we departed they gave us a kind "adios."

St. Helena, 18 miles from Napa, is another of those beautiful towns we have so often observed. Like Napa it is surrounded with vine-

yards, and boasts of one of the largest wineries in the State. It would have been very pleasant to camp in such a town; but thinking we might get among the festive Spaniards again, we pushed along. Our friend H. L. Jones, the gas-man of San Francisco, having our welfare in mind, said we would find a beautiful camping-place beyond St. Helena—streams of running water; fir and madrone trees interlocking their branches, making a cooling shade, and, above all, it was near the residence of his friend W. M. Cole.

We found the camping-place all he had pictured it, and Mr. Cole was a Missourian of the "walk right in and help yourself" order. It seems that he delighted to have the camping public rest under the shade of the trees. For his special friends he had a cosy nook on the banks of the stream near his residence, which he offered to us; but as we were to stop only one night we preferred the more public place near the highway. Mr. Cole's house was so embowered under fruit-trees that but a small portion of it could be discerned. A thriving family of boys and girls were romping among the trees. As to how Mr. C. was getting along in other directions, I know not; but in the matter of a family he was a success—not the evidence of things hoped for by some, and not found, but here was evidence and reality.

Mr. Cole was a bee-keeper after a fashion. He allowed his few colonies to manage things their own way in the far corner of his garden. They held proud possession of a few cracker and soap boxes, and, according to Mr. Cole's ideas, they were a strain of bees known as the French bee. One of their shining characteristics lay in their fighting qualities. A neighbor across the valley brought in some Italian bees; but the French bees pitched into them. They had a general fight, and "fit and fit," and the French bees came off victorious.

"But I ain't no bee-keeper," said Mr. C. "I kin go out into the woods and get more honey than I can from my hives. These French bees work better in trees than they do in hives, and the woods are full of bee-trees." Said he, "You tell Harry Jones, the gas-man, to come right

out here and set up a bee-corral. It will pay him."

Mr. C. made some complaint about moths getting into his hives of French bees, and didn't see why, when they were such good fighters, that they let that pesky moth in to eat up a whole colony. Then grapes and French bees did not agree. In his little vineyard of choice grapes he left two rows for family use; but the French bees got after them after awhile, and cleaned them all out, and left nothing but the shucks.

Mr. Cole's swine-corral was located near the bees, and the pen and the hives were elbowing each other, as it were, for room. This led to a discussion in relation to hog and honey production vs. hog and hominy. I told him our gaseous friend in San Francisco proposed that line of labor.

"Just the thing," said Mr. Cole. "This is the best hog and bee country north of the city; and such an energetic fellow as Jones would make things lively up in this country. As you observe, my bees and hogs agree well together. And say, stranger, did you ever know of a bee stinging a hog?"

I had to confess that, though I had seen many hives located near hog-pens, I had never witnessed or heard of such a case.

"Well, it's a fact, sir, a bee will never sting a hog. If you get the scent of a hog on your hands or clothing it is the best of preventives to bee-stings. Smokers! wouldn't have one around. Just step over into the pen and rub your hands on the old sow's back, and you will have apifuge enough to last half a day." Unfortunately I am not so situated as to test Mr. C.'s plan. But when Mr. Jones gets his ranch started, and has several fat sleek porkers near at hand he can call up Peggy, Betsy, or Hannah, as the case may be, and secure the apifuge. It is quite possible, though, that the hog antidote could be successfully practiced with only our friend's French bee.

There were other small apiaries in this vicinity, but they were not numerous, and not managed according to modern methods.

Our fine camping-place was made desolate again in the morning, and we were rolling through that other beautiful town, Calistoga. The attractions of this resort are sulphur springs, mountain scenery, and climate. The vineyards shade off here into prune-orchards, which, healthfully and morally, is a good shade for the people.

Our friend Jones, of gas memory, had, at some preceding time, spread himself all over this country; and, knowing what he was talking about, he advised us to cross the St. Helena Mountains to Lake Co. by what is known as the Oat Hill route. We followed his advice, with "childlike and bland" confidence. We had an arduous climb again, winding up and around the mountain-spurs. As we were lifted

by the grade high above the Calistoga Valley, a scene worthy the artist's brush lay beneath us. The level valley is broken in many places by quite sizable hills; these, covered with trees and luxuriant deep-green foliage, looked like so many islands rising in the midst of vineyards, orchards, and homes, while the distant Coast Range gave a fitting background to the lovely landscape. I was also told that a view from this mountain road was peculiarly pleasing and novel when the fog was resting low down in the valley, every thing being hidden from view except the projecting hills, and the appearance was that of a large lake dotted here and there with islands. On the mountain summit we found a cabin and a refreshing fountain of water, where we were glad to rest our horses and eat our noonday lunch.

The geological outcroppings here were of a hard and stern character. The rocks were jagged and pointed, and we could imagine many an ancient castle with its towers and battlements frowning down upon us. Such a geological upheaval would naturally presage something of an unusual character; and here upon the northern slope of the mountains we find a profitably worked quicksilver-mine, known as the Napa Consolidated Mine. Quite a little town is perched here upon the rough and rugged side of the mountain. There is scarcely room for dwellings; but by digging out niches, removing boulders, and placing long stairs, the thing is accomplished. The mines are owned by 300 stockholders, all Maine capitalists. The laborer earns all the way from \$2.00 to \$3.00 per day, and quite a sprinkling of Chinamen are employed. The shafts, or tunnels, are run in horizontally from the side of the mountain; and little trucks, with a donkey attached, run out the ore to the smelter. Around the latter, where the fumes of mercury rise, is the only unhealthful place to work, and much of this is overcome by wearing sponges over the mouth and nose. It is said that corporations are soulless; but it seems that this corporation has a soul in the direction of temperance, and, let us presume, in other directions also. The stockholders, being Maine men, have brought the prohibition principles of that most Eastern State, and planted them here among the hills of the most western of our family of States; and, though great inducements have been offered to allow liquors to be sold in the only store, which is owned by the company, it is not allowed, and is kept from the grounds as far as possible.

A few miles beyond the mines we found a fine camp beneath the outspreading arms of oak-trees. Here we quietly rested over Sunday, the 26th day of August. Bro. Wilder, taking Rom. 14:5 for a text, went off in the morning early with his rifle, in search of signs of deer. There were some sheep around that country, so the signs, supposed deer-tracks,

were plentiful. He also found another fellow with a rifle who had strangely taken the same text; and when they returned in the heat of the day the signs on their faces plainly echoed the words of the Preacher when he said, "Vanity of vanities, all is vanity."

We are now in Lake Co., called by the inhabitants the Switzerland of America. We had previously heard of so many Switzerlanders of America that we suspected these people were hallucinated by local pride, and we resolved to have a lookout for the grand features. Our first day in the county was not favorable to Swiss impressions. It was hot, 108° in the shade, and the roads very dusty. After a long drive, wherein we could find no water for our ponies or dog, we made Lower Lake—tired, hungry, and dusty, and straightway camped.

HONEY AS A DIET.

A REPLY TO C. DAVENPORT, PAGE 217, MARCH 15.

By Thaddeus Smith.

I wrote the article on "Honey as a Diet," printed on page 92, which, through some oversight, appeared without a name to it, and upon which Mr. Davenport makes some comments and criticisms. Mr. D. says he does not agree with me, that a great many people do not like honey or care for it as food or a relish. He finds no dislike for good honey in his locality; but my experience in a different part of this wide country has been the reverse of his. We may both be right, and the apparent contradiction may be owing to the different location and the different class of people we have come in contact with. Mr. D. thinks that only those who never saw good honey dislike it. I can assure him that the good lady who gave me her reasons for not using honey on her table knew what good honey was, and I am confident that most of the persons I have alluded to have have had opportunities for seeing and tasting good honey—fine white-clover honey. I have known some progressive bee-keepers who care but little for honey, and do not use much of it in their families; and in the article referred to I called upon bee-keepers, especially those at the "Home of the Honey-bees," to give their testimony as to the amount used in their families. If Mr. D. had read carefully he should not have made the mistake of supposing that the editors wrote the article.

HONEY AT HOTELS.

In a recent trip to Florida, of six weeks, I did not stay long at any one place, and consequently was a patron of many and a variety of hotels. The bill of fare at most of these hotels contained a great variety of all the substantial and delicacies of the season, usually including maple syrup and other syrups; but I found honey on the menu of only three of the hotels that I stopped at. It so happened that I

took a breakfast at the grand Tampa Bay Hotel (cost one dollar and fifty cents), and there I found "orange honey" on the bill of fare. But there was such a grand array of good things displayed on this menu that I did not call for it.

At Atlanta, Ga., I also found "orange honey," and this time called for it. I was brought a dark liquid resembling Florida syrup—fully as dark—which had a bitter and astringent taste. I could not eat it, and called for maple syrup. At another hotel I got some comb honey. The comb was white and tender, but the honey was darker than any fall honey I ever saw in the North. The quality was a great improvement upon the first, but not up to our standard. I should like to hear from A. I. Root in regard to the honey he found in Florida.

UPWARD VENTILATION WITH A VENGEANCE; A SINGULAR CASE.

A friend in Kentucky kept bees many years ago. Thirty years ago he had some of his bees in movable-frame L. hives, and a very nice little apiary; but in the pursuit of other matters he soon lost interest in them, ceased to care for them, would not have new swarms or have any one else do it. He had so completely abandoned and banished them from his mind that he did not know whether there were bees on his farm or not when I visited him last fall. I looked around his place where he used to keep his bees, but could see nothing left of the old frame hives except the body of one up in the garret of his two-story house, where a fine colony had once flourished and stored large quantities of surplus honey. The hive contained the litter of the combs, eaten up by mice and moth. The frame hives outside were all gone, but there were a few remnants of box hives, some partly broken up, some filled with moth-cocoons, and one without cap or cover, with live bees in it. All were nearly rotten. I do not know positively how long these bees have been in that hive, but I think they have been there 12 or 15 years, and probably longer. The hive had a $1\frac{1}{2}$ -inch auger-hole in the center of the top—uncovered—exposed to rain and snow. To protect them a little I kicked an old hive to pieces (and it was easily done), and laid one of the pieces over the top, with a stone on it. But as there were some strips on top of the hive the board did not fit down close to the hole; it was still open. So much for the introduction, now for the sequel. My friend, his wife, and myself went to Florida. They will remain there until April. I returned March 5th, and am staying at their house with their two sons. I went to look at the bees, and found the hive turned completely upside down, without any cover over it; but the bees were alive, and seemed to be quite strong. I called up the colored man, who seems to be a kind of foreman while the owner is away, and asked him what he knew about the bees. He said, "I

reck'n the mules must have knocked it over; they were in the yard here the other day. They knocked it over once before in cold weather, and I turned it up again." But he could not tell me how long it remained turned over either time. In another place, in the orchard, March 12th, I found another box hive turned upside down and full of comb, no cover on it, and, to my surprise, there were live bees in it. I carefully turned it up and sought the colored man again, who, by the way, is quite intelligent and very reliable. He said the hive had been in that position all winter; he thought the bees were all dead, and he did not pay any attention to it. From the indications around it, and the impression on the grass, where the hive stood, I am satisfied that it did stay in that position all winter; and this has been the coldest winter known here for many years. In December the thermometer was 14° below zero, and in February 18° below, and either down to zero or below every day for three weeks in February. This is a case of extraordinary upward ventilation, and shows what an amount of exposure bees will sometimes endure. But why is it that this is only *sometimes*? There must be some cause for it.

I have a theory in regard to this particular case. There was a great deal of snow—ground covered all the time of the cold weather, and no rain all winter. The combs were level with the bottom of the hive (now top), old and strong, and became covered with snow which remained until warm weather, it being too cold for the heat of the bees to melt the snow above them. This was some protection to them during the coldest weather; but when this melted off they remained in that unprotected condition up to the time that I discovered them. March 19th I examined the hive to see if the bees needed feeding; and in raising the box up, every comb in it dropped out. The exposure to rain, snow, and frost had loosened all the combs from the box. The colony was not large, and there were but comparatively few dead bees. Two combs contained large patches of brood, and they still had plenty of honey. I transferred them to a clean box, and they are doing well. These hives are cases of extreme ventilation, and of upward ventilation at that. They wintered well, but probably will not decide the much-mooted question of sealed covers or upward ventilation. I merely give the facts, without entering into the discussion.

Midway, Ky.

[In regard to the honey I found in Florida, I would say I saw little or none on the tables of the hotels; but I found beautiful honey in great plenty at the homes of all the bee-keepers. I do not think I saw any poor honey even once. Very likely they brought out the best, or saved up some of the best for me. I learned to be very fond indeed of honey from saw-palmetto. And that makes me think I am guilty of putting a wrong title under cut on page 146. It should be saw-palmetto and not cabbage. The cabbage-

palmetto does, however, furnish good honey also. Honey from mangrove and that from saw-palmetto were pretty nearly the only two kinds I found. The honey from orange-blossoms is so often mixed with that from other sources that it is a pretty hard matter to get it any where near pure, as a general thing.—A. I. R.]

HOW TO CONVERT OLD BROOD-COMBS INTO FOUNDATION WITHOUT MACHINERY.

A NOVEL IDEA.

By W. M. Little.

During the past season, 1894, I succeeded in working over old brood-combs to my complete satisfaction. I had about 200 old combs, that had been in constant use for 12 years. I tried rendering them, but could secure but little wax from them, as the cocoons and other substances absorbed all of the wax, and I had nothing left for my labor. So I began to experiment a little. I began, with a sharp Bingham honey-knife, trimming down the cells of these old combs (some of them were old transferred combs taken from old box hives ten years ago). I soon found I could cut through the cocoons down to the septum by care, and leave the base of the cell intact; then, turning the L. frame over on a board, cut the right size to fit the frame, thus supporting the comb, and I could trim down the other side in like manner, leaving a sheet with the base of the cells well defined. The bottom of each cell will be filled with the base of the cocoons of all of the past generations bred in them; these, however, the bees remove in a short time, leaving the septum much like the sheet of foundation at the first. If the sheet is torn, or if there are patches of drone comb that I desire to dispense with, I cut it out, and patch it with brood foundation, using melted wax to hold the patch in place until the bees fasten it permanently.

I succeeded in getting 150 combs of this kind rebuilt in a few days in the early part of June last, before the honey-dew began to be gathered by my bees, when they would not build comb of any kind. These combs were mostly built on wired foundation in the first place, and, having been rebuilt, are firm, and stronger than those built first on foundation. After working at cutting these combs down I became quite expert at it. It takes a keen, stiff knife, using cold water to keep the septum stiff, so that it will not stick to the blade, and tear. With a little experience at the business, one can trim them down quite rapidly, and can make brood-combs much more rapidly, and with less waste of wax than by rendering the combs and molding them again. The bees seem to delight in pulling out the base of the old swaddling-clothes of former generations of bees, and mending the rents and patches in the old comb, and working them over.

If my health permits, and the bees have work to the coming season, I will work over a large

number of my old combs this year, as I am well pleased with the result of my experiment last year.

WM. LITTLE.

Marissa, Ill., March 9.

HANS READS A. I. ROOT'S BEE-BOOK.

I reads dot book dru ant dru,
Und I studies it ore and ore,
Mine het it vas most bustin.
I c'n not stand upon der floor.
I reads about dot Doolittle,
Und pee-mons by der schore;
I yust can not sit sthill,
I gets me yup and vakes der floor.
I goes to see von nabor-mon,
He gots do, dre'e hifes or more,
He dells me ne dot does bee-mons
Dravels der gundry ore.
I studies dot bee-book in und oud,
But I denk does bee-mons
Knows vat dere about,
Does bees make you look a little oud.
Und as I reads dot pook
I denk, "Hans, you get some bees,
Und dry your luck mit huny,
Und hife dem in der trees."
I gets mine bees from Alley,
Dot new fan-dan-gh d kind;
He says dey makes der most hunys,
Und works quite to der mind.
I gets my hives all redy,
Und fix d-m out among der trees.
Und I denks "Now, Hans, you bees happy
Mit your lofly little bees."
Does bees comes out
To haf a li the fly
Shimney Gristmas!
Oue sthicks me in der ey!
Dot ey it keeps a swellin,
I can not see no more.
I denk I fix does bees;
I shmoke them do, dre dimes or more.
Does bees dey come a pilin out,
And I runs me all about
To get der hifs all redy
For does lofly little bees.
Does bees crawl up my bant legs,
Und sthings me on der knees,
I runs arount most gracy,
Und get some vater for does bees.
I dink does pees of Alley's,
He says dey bees so kint,
When dey gets a sthinging me,
Dey works quite to der mint.
I hife does bees do, dre'e times or more;
Mine hart mit dispair vas akin,
For yust so sure I haf dem rite,
So sure I vas mistakin.
I c-lls mine wife to help me oud,
Mide demper vas most rilin,
Ven oud gomes does bees
Yust a bilin'.
Then I say, "Hans, you bees a fool,
To be so long a lookin,"
So I gets me in dot house,
Und gets dot book to look in.
Does bees flies round and round,
In does trees dey sthop not eny;
Mine vife she say, "O Hans!
Der bees so very meny."
I gets does bees right in dot hife,
They goes to makin huny;
I say, "Now, Hans, ol't poy.
You ged your bokets full of muny."
I reads about dot Rambler,
Dot funny mon is he;
He no likes the vimens,
But he lofes dot little bee.
But now I bees so happy,
Dot book it helps me oud;
Und I studies it some more,
To knows what I bees about.
I denk does bee mon's
Heads is level dot rites
Dot book about der bees;
It has helped a greenhorn yust like me.

HANS VONDERBLINKEN.

COGGSHALL'S SPRING MANAGEMENT.

ONE DAY'S WORK AT THE OUT-YARDS OF AN
EXTENSIVE AND PRACTICAL
BEE-KEEPER.

By Harry S. Howe.

On Thursday, May 10, 1894, I received the following card from Mr. W. L. Coggs hall:

Friend Harry:—Come over Saturday, and help us make the grand circuit, if weather is favorable. Apple-bloom is nearly over. W. L. C.
West Groton, N. Y., May 9, 1894.

With me the apple-bloom had been for some time over, for I was teaching at that time twelve miles west, near Cayuga Lake.

We always wish to unpack the bees just at the close of apple-bloom, for there is nothing to gather for a time then. If they were unpacked during the flow, they would lose a day or two of honey. There is sure to be a slacking-up of brood-rearing at the time of unpacking, and also when apple-bloom is over; so we bring the two together when we can, for they are not apt to slow up much more for both than for one alone. Of course, the weather has also to be consulted in regard to the best time to unpack, for it would not be well to set them out when a cold wave was expected, even if they had to stay in another week. This time, however, the weather was all that could be desired.

When school was out Friday afternoon, I got out my wheel, and arrived at Mr. C.'s house in time for supper. After supper, Mr. Coggs hall, Russel, and I sat down to talk over the campaign for the morrow. Just here, perhaps, is a good place to introduce Russel Stennet, a young man from Virginia, who came North to put the finishing touches on his education as a bee-keeper. This was to be his first trip to the south yards. After talking a few minutes, Mr. C. remarked, "Well, Harry, I have started a new yard this year again."

"Where?"

"In that nice location near Etna we talked about last year."

"Why did you like that better than the others?"

"It is near the station, and will make a good place to store the honey from the other south yards, if I do not want to ship right off early."

"Yes, I remember that we figured out that the Etna station was the nearest one to most of the honey. By the way, how are we going to-morrow?"

"We will take the team and democrat wagon. It would be a rather big load for the buggy; besides, I want to take some smoker fuel."

"When were you at those yards last?"

"I have not been to Ellis since they were packed last fall."

"What time shall we set the alarm-clock?"

"It is a long drive there. Perhaps we had better start by six; that would get us up by five."

After some more talk on bees in general, we went to bed. The next thing I knew, the clock

was ringing away for us to rise. The chores were quickly done, and the wagon run out and loaded with the things that were to be taken. After breakfast, came the seven-mile drive to the Brown yard. Arrived there, Mr. C. showed Russel where to put the team, while I unlocked the honey-house and lit the smoker. The supply of fuel for the season was put in place, and a box of matches in the match-box.

The fifty colonies at this place are in chaff-packed Eclectic hives. It took but a short time to take off and pack away the cushions from the tops, and see that there was no loss. The bees were apparently in need of nothing, plenty of honey having been left the previous fall.

Russel and I put the team out while Mr. C. went over the yard to see that every thing was all right, and that no fire had been left. Then the three miles to Etna quickly passed, where the same business with the team was repeated. This yard required more work, however. It was put in place while the snow was on last winter. Some of the bees were drawn from other yards; others were bought. Those new ones were not in the best shape for rapid handling. The combs of some had grown together so they had to be cut apart. The five miles of road to Ellis is over a high ridge of hills, the last two miles over an old wood road upon which three or four families have settled. Russel said that it looked much as it did down home in the mountains, where they have done no work on the road in years. The land on each side had been covered with pine, which had been cut off, giving place to thickets of chestnuts and brush. The Ellis yard, however, is situated in a fertile valley. We ate our dinner, which we had brought along, before beginning work. For a cold dinner we have found nothing to equal good bread and milk. This time we had a loaf of Mrs. Coggs hall's bread, and she can't be beat as a bread-maker. A two-quart can of milk, some strawberry sauce and cookies, taken together, makes a meal which a king might envy. When I go on my wheel, I take my dinner with the people we rent the yard of; but it would not always be convenient for three to drop in on them just at meal time.

This yard of 67 live colonies was set out in a hurry. They are in Mr. C.'s own style of packing-case, which he will describe for GLEANINGS soon. The places where the stands stood were plainly marked in the grass. This yard is the hardest to reach, but every thing is so handy when we get there that we do not have to stay long.

We are now fifteen miles from home, and two o'clock finds us on the road back over the hill. The road we take is, if possible, worse than the one we came by; but we are at Varna at last. Here the work is much the same that it was at Ellis, except that about 40 of the 90 live ones we find are in chaff hives, which do not have to be

handled. When this yard is finished, we drive home rather leisurely. Just after sundown Mr. C.'s little boys stop from their chores to shout, "Here is papa!"

We had driven over thirty miles, unpacked 131 colonies, besides going over 110 colonies that were in chaff hives.

We have a regular system upon which we work, not only in unpacking, but in all the work with the bees. To do rapid work, one must have, first, handy hives and fixtures; second, a system that fits the hives; third, men who are used to both. In the case of that big day's work we had hives of two entirely different patterns, neither one of which has proven itself so superior as to drive the other out of use.

We had a system that is the result of over a quarter of a century's constant effort to systematize the work. We had two men who had worked together more or less for seven seasons; the third was an experienced bee-man, quick to learn, but he had never worked on that system before. We go to work as soon as we reach the yard and every thing is ready. The first step in unpacking is to place the bottom-boards. These are loose. They are placed where they stood last year. They can be told by the places where there is no grass. One man carries them out from the honey-house, where they had wintered, and sees that they are level from side to side, and tipped slightly forward. The others take off the covers from the packing-cases, which hold eight colonies, and place them near where the empty cases are to stand, then the hives are lifted out one by one, after being slightly smoked at the entrance, and placed upon the stands. Care is taken to place the weaker ones where the cases stood, while the stronger ones are placed on the ends of the rows. The empty cases are placed out of the way, but handy for the following fall. The covers are carried out and placed on them, and that is the end of that boxful. This is repeated with each box until all are out. The hives are all looked into to see that they have a queen, etc. Sometimes the one who is looking through the hives calls a consultation of doctors to see what to do to some one that is out of the regular run, or perhaps it is a coroner's jury that is called to find the cause of some mysterious death. Mr. C. himself, however, is rarely at fault in such matters, his long experience enabling him to see at a glance what it would take one of his younger generation hours to study out. He is always willing to impart his knowledge to those about him.

The work of the day goes along without many directions being given. Once telling in the morning is supposed to be sufficient; in fact, Mr. C. very much prefers to have experienced help. Of course, when he has a green hand, he has to keep watch of him and see that he is working to good advantage. The things that are used during the day are all picked up at

once. It seems to be cheaper to drop empty hives, extra covers, etc., where they happen to be, and then carry them all in at once, than to make a separate trip for each article.

Mr. C. says that he is handling bees for the honey, and that, if he can work faster or easier by having things handy, he is going to have them so. He carries his system of rapid work to his farm, and even to the harness. There are no buckles on his harness to unbuckle; those places are all fastened with snaps. His idea is, to get a good system, and then stick to it, study it, perfect it in every detail until you can do your work with the fewest possible motions and the least expenditure of time and strength. One of the best ways to make bees profitable is to reduce the cost of the production of honey.

Groton, N. Y.

PRODUCING COMB HONEY A LA FRANCE.

CAN IT BE PRODUCED OVER TWO EIGHT-FRAME BODIES?

By E. France.

I am asked to give my plan for producing comb honey. I suppose you all know that I am not a comb-honey producer usually, although I have raised some. I have been thinking of working a part of my home yard for this purpose, but I have not got at it. Several years ago I got 100 supers, right size to fit my hives. They hold 24 sections each. I got 4000 sections. I have the most of them yet.

The question that is put to me is this: How would I produce comb honey, using a two-story eight-frame brood-chamber? This would depend on circumstances. If the bees gather and store that much, I must have eight frames full of good sealed honey to winter the bees first; then if honey is coming so they can store more, I will have it put in sections; confine the queen to the lower story with zinc, then put on the sections with foundation starters; put the second story of eight frames full of honey on top of the sections, if the colony was strong. I think it would be best to give them two supers—one over the other. I would not put on the second super of sections at first. Wait until they get crowded for room. As fast as the sections are completed take them out. Give them plenty of work to do between their winter stores and the brood-nest. I am keeping their winter supply overhead to save it. If the frames of honey were below the sections, the bees would likely put some of it up in the sections, and I don't want them to do it. I want to give the bees their share, and I will take what I can get after they have theirs.

If the colony is strong they may swarm. If they do, put the queen in a cage, and put her into one of the upper sections, after removing all queen-cells; then in ten days remove all queen-cells again. In ten days more, liberate

the queen. I have tried this plan with six colonies. In 1886 I got both supers filled with honey—48 sections.

Another plan. As I am working for extracted honey mostly, with three sets of combs, I made the extracted bees feed the comb-honey bees. In this case I don't wait for the section bees to fill the combs to winter on, but put the sections on earlier, and not have the combs above them—just sections with the honey-board on top of the sections, queen below the zinc in the lower story. Give them all the sections they can fill, to the very last of the honey season; then take off all the sections and zinc queen-excluder; put on a second story, and fill it with full combs of honey from the third stories of the extracted bees. This plan gave the most section honey; but they are more liable to swarm.

Bees could be worked on this last plan, and then give them a set of empty combs, and feed sugar syrup for winter feed. But for me I like the honey best. I was forced to feed my bees 14 barrels of sugar in the fall of 1892, and that winter I lost 160 colonies of bees—a greater mortality than any year before or since.

Now, I don't know but the comb-honey men will laugh at me, or at my way to get comb honey; but I don't know any better. Remember that location makes all the difference you can imagine. What is best in one place would be folly in another.

Platteville, Feb. 27.

BEE-KEEPING IN THE TROPICS.

SOME INTERESTING ITEMS RELATIVE TO BEES
IN GUIANA, ETC.

By Thomas B. Blow.

Dear Friend Root:—I wrote you some months ago that I was going to take a complete change this winter, ill health having been troubling me much for the past year; and I said that, if I saw any thing of interest in the West Indies or elsewhere, I would write you. You very kindly sent me letters of introduction to all the people you knew in that part of the world. I received these at Trinidad, and you have my heartfelt thanks. I was, however, prevented from going to the larger islands, where those bee-keepers lived. My route was to British Guiana via Madeira from London, and I found that very little bee-keeping was carried on there—none commercially. There are two or three bee-keepers in Georgetown, with small apiaries, and their bees are kept in rough boxes or rough hives, with American frames. There appears to be a moderate yield of honey; but owing to the great equality of the climate the year round (the variation not amounting to more than 10 degrees of temperature) there is nothing in the shape of a harvest as we understand it. The bees I saw were all descendants of imported bees, and greatly resembled Carnio-

lans. There is a wild bee here of the genus *Apis* (about half the size of *Apis mellifica*), stray swarms of which often take possession of an empty box in an apiary. They, however, yield but little honey, and are few in numbers compared with a colony of common bees. After seeing some of the sugar-factories here (for sugar is the greatest industry here, though at present in a very bad way owing to the great competition with German beet sugar, many of the estates being abandoned; for, though they are in a high state of cultivation, and some have upwards of \$500,000 worth of machinery in the factories, yet they are quite unvaluable), I proceeded to see the gold-mines, which are becoming quite a great industry. They are, however, rather remote from civilization, the nearest being between 200 and 300 miles up the Essequibo River and its tributaries, most of the ground they occupy being part of the territory so long in dispute between Great Britain and Venezuela. The only way to reach them is by open boat rowed by (or, rather, paddled by) about twenty colored men; and as a great many rapids and falls are encountered, it takes about seven days to accomplish the journey. Each day, when we halted the boat for the midday rest, I went into the bush as far as possible, to see what bees I could find. There were great numbers of the small stingless bees (*M. trigona*) that store their honey in little bladder-like receptacles; and at one place I noticed quite a number of bees, pollen-laden, at a creek, taking water. They much resembled Carniolans, but were fully a third larger, and much more hairy. I was sorry that time did not allow me to trace them to their nest. This journey, botanically, was most interesting; for at the rapids, which are the only parts of the river that support any vegetation at all, I was able, during the time the boat was being drawn up, or portages made, to study the habits of about three species of *Podostomaceæ*, of which very little is known.

Altogether this journey was a great treat. The camping at night, our hammocks swung between the trees, and the numerous campfires, with the men cooking their evening meal, was something quite new to me.

Leaving the South-American mainland, Trinidad was the next point of call; and, though so beautifully written about by Charles Kingsley, in "At Last," yet I somehow failed to appreciate it, and I was rather glad, at the end of 12 days, to make ready to depart. There are a few bees kept near the town, and quite a lot in Maraval, on the Mocha estate there. Their owner is Mr. Watkins, who hails from near Hereford, England, and I had a real good time with him. Mr. Hart, the government botanist, keeps a colony of the stingless bees (*trigona*) near the door of his laboratory; and he told me that at dusk each evening the entrance of the hive was sealed up by the bees to prevent intruders entering during the night. Granada,

St. Vincent, St. Lucia, Martinique, Antigua, Nevis, St. Kitts, and Redonda, were visited; but the last and most interesting was Montserrat. I was here enabled to make an interesting observation as to the quantity of beeswax produced in a given area. The island is quite a small one—30,000 acres—with a population of 9000. Bees are kept to some extent, but I imagine a quantity of the wax is got from the wild bees in the forests on the mountains. I had the good fortune to be provided with a letter of introduction to a gentleman who is practically the sole buyer of all the beeswax that is exported. The whole appears to be brought to him with the exception, perhaps, of a little that the chemist gets for local use. The average quantity is about 1120 lbs. per annum, or about 1 lb. to every 27 acres. This island is in a better position than any other I visited, for the production of comb honey, owing to the vast plantations of limes, the property of the Sturgis Montserrat Lime-juice Co. The honey is very superior, being much like the South-European orange-bloom honey, and commands quite a high price locally—about 5 cts. per lb., being put up in empty whisky-bottles, which, I compute, hold about $2\frac{1}{2}$ lbs. each. The surplus honey finds a ready market in Trinidad.

I here found my time was exhausted, and was hence obliged to give up any extended visit to Cuba, Hayti, and Jamaica, which, of course, are the great bee-keeping islands, and I am writing this at Barbadoes, on my way home.

[I will explain to our readers, that Mr. Blow is one of the leading-supply dealers in England. He has traveled extensively throughout Continental Europe, and to some extent in the United States.—Ed.]

JELLY-FISH.

AN INTERESTING DESCRIPTION OF THEM

By J. W. Buel.

The *Discophera* (disk-bearers), such as jelly-fish, sea-nettle, etc., are a very numerous, attractive, and (under some circumstances) troublesome community in the waters of the ocean. They seem restricted to no temperature or climate. They exhibit the most infinite variation in size, form, and color. Many of them add to their personal charms the phosphorescence which is so charming a feature of evenings at the seaside. Their delicate tissues assume all imaginable forms, and rival the magic of the kaleidoscope. The arms proceed from beneath the umbrella-like disk, and resemble the four posts of some grotesque arbor. The mouth, when existing, is placed in the lower wall of the disk, and is furnished with tentacles. A common species has a multitude of filamentary tentacles which resemble a fringe dropped from the seat of a chair; these it entwines about any object of contact. As each one of them is endowed

with the ability to sting, it can make its presence felt, and its memory a "possession for ever." One species is frequently two feet in diameter, and moves about in schools, or shoals, which oftentimes are sufficient to interfere with the progress of boats. Irridescent in the sunlight and phosphorescent in the twilight and darkness, their course is a path of light.

The jelly-fish is the glass-umbrella of the sea, and in place of the handle are numerous delicate filamentary tentacles. By the contraction and expansion of the muscular umbrella-like body, the creature makes its way through the water. Its tentacles, however, contain a sting and a poison-cell, so that, while admiring its beauty, one must remember the maxim, "Do not touch me."

All animals' bodies are partially water; but the jelly-fish contains only about thirty grains of solid matter out of a possible ten pounds of weight. Many a person who has admired the beauty of the floating jelly-fish has been surprised to find it almost vanish after it had been caught. A story is told of a thrifty farmer who collected loads of jelly-fish, thinking to fertilize his land therewith, but found that he had rather discovered a new method of salt-water irrigation.

DRUGS FOR FOUL BROOD.

WHY THE OPPOSITION TO THE DRUG METHOD.

By F. L. Thompson.

At various times in the past you have said that you took no stock in drugs for the cure of foul brood. I differ with you, if you meant that drugs never cured foul brood. We have had cases enough, with three different drugs, to prove that they do. Cheshire and others (among them one of our county inspectors) have succeeded in curing foul brood with carbolic acid; Ed. Bertrand cured 37 colonies with salicylic acid; and others in Switzerland have recently succeeded with formic acid. In the face of such evidence we are justified in simply disregarding the assertion which Mr. McEvoy and others make, that foul brood can not be cured with drugs.

But it seems a little singular to me that energy should be wasted in these fruitless assertions when there is another evident loop-hole by which the drug cure (for that is the proper term) can be attacked; namely, its great slowness. Even lysol, for which so much is claimed, took three weeks to effect a cure. Now, if one man's sick colonies were all he had to look out for, the drug cure would be the thing, though it needs skill and thoroughness, as many have failed with it; but when there is danger that not only his remaining healthy colonies, but also his neighbors' bees, will be infected, while he is putting over his drug cure, it is evident that we, as a community of bee-keep-

ers, can not allow it. There is nothing better than the old way of inspectors and transferring, or possibly the Baldrige method as amended in the August *Review*.

But where I am criticising you, Mr. Editor (and nearly every writer on the subject, for that matter), is right here: Here are all these drugs, of such *proven* efficacy in their relation to *Bacillus alvei* that they will stamp it out, even when it has accumulated in such proportions as to cause the death of the brood; and, on the other hand, there is foul brood itself; and no one who has not been through the mill can realize what a disagreeable job it is to deal with, not to speak of the loss. Is there not the strongest kind of presumption that some one of the drugs mentioned can and ought to be used as a preventive by bee-keepers who are anywhere near foul brood, and that every contribution to drugs as *cures* ought to be eagerly welcomed, whether slow or not, for the good it may do in *prevention*? Our wise shakes of the head ought to be reserved for the impractical method of relying on drugs, without transferring, *after* the disease has obtained a foothold.

So much for *a priori* grounds. Are there any *a posteriori*? Yes, and good ones, though not extensive as yet. I have not at hand the number of the *Progressive* (page 76, 1894) which contains what I refer to; but the following is Mr. Hasty's comment: "D. L. Tracy, of Denver, makes a success of preventing foul brood by the use of dilute carbolic acid. For four years neighbors all around had it badly, and he escaped. He merely sprinkled heavily the *tops of the frames* three times each breeding season. Formula: Carbolic acid $\frac{1}{2}$; salt $\frac{1}{3}$; water 296. □ (One part of carbolic acid to 300 of water, and a level tablespoonful of salt to every pint of the mixture is an easier way to remember it.) Easy enough to try. But don't put on fire-proof paint as a preventive after your building is all ablaze at one end. That's about the way half the boys would do—if they did any thing." But that last statement should not be construed to indicate that preventives should not be made known for fear they would be taken as cures. The rest of us ought not to suffer, even if some men are fools.

The first year I began bee-keeping I had to transfer all I had—20 colonies—on account of foul brood. Being a novice, and pressed with other work, my colonies were so weakened that they took until the fall of the second year to build up; and the second spring after, the spring count was 7 to show for the original 20. A knowledge of a preventive, and a sense of the desirability of using it (which the bee-papers do not give) at the time I bought my bees, would have saved me \$100 at the least. It is a terrible mistake, sometimes, to be too cautious, when nothing would be lost by venturing.

Let us admit that a colony in full robbing career would contract the disease anyhow, pre-

ventives or no preventives; still, the evidence that the preventives would make a great difference in the degree to which that colony would be afflicted is strong. Compare Mr. R. L. Taylor's occasional plan of holding the dread disease in check by the use of medicated feed until the close of the season—not that such a procedure is to be recommended; but for evidence, it is just what we want. But in the majority of cases it is probable that the disease does not begin by excessive robbing. A taste here and there, and a bee entering the wrong hive occasionally, are mainly what we have to look out for, and are precisely the conditions which we have very strong reasons to suppose would be rendered harmless by those drugs which have been able to effect cures.

Mr. Adams, the inspector for Boulder County, who constantly uses and recommends the formula referred to, and can furnish other evidence besides what I have given, spoke of it at the meeting of the State Association last April, but said plainly that he did not recommend it as a cure. After learning about it I told a near neighbor, who had about 250 colonies among which he had discovered two cases of foul brood shortly before, that I would apply the method to the rest if he would furnish the materials. He agreed, and I did so. Neither his bees nor mine showed a trace of the disease last season. Perhaps they would not have done so anyway; but who knows? I do know this, though; that, if the disease had spread among those 250 colonies with the same rapidity that it did among my 20, the labor, the loss, and the vexation would have been enormous.

Another use of drugs, and an important one, is in treating colonies *after they have been transferred*. That is the very time when, if by any hook or crook—a drop of foul-broody honey should be left exposed, they would be apt to get it; and such treatment is especially desirable when, for any reason, the remaining colonies have to be transferred during the day, instead of in the evening—and that is quite often the case—when there are many to attend to. Experience soon shows that the assumption, that more than a very, very few colonies can be properly transferred by one or two persons, after the bees have stopped flying and before it gets dark, is fallacious. Robber-bees fly as late as they can see, anyhow; and the average bee-keeper can not muster a gang of men for this business, even if he could afford it. Here is where the Baldrige method, if approved will be a boon indeed. I transferred most of mine during the day (after a few frantic and unsuccessful attempts to do it up in the evening), and fed a part of them with medicated honey, after boiling. At this time the bees had begun to show a slight propensity to rob, the main flow being over. If I had to do it again I would sprinkle the hives of all after transferring, and give medicated food to all. The next

spring but two colonies showed slight indications of foul brood, and were again transferred. If I had known of drugs as a preventive, perhaps not even that much would have reappeared.

"An ounce of prevention is worth a ton of cure," said one of our Denver bee-keepers, referring to foul brood; and every one who has had it among his bees will say amen. The question becomes doubly important when we reflect that, as Mr. Getaz suggests, whatever cures foul brood will probably cure paralysis, and therefore prevent it. No, sir; we can not go back on drugs yet. I move that the bee-papers change their attitude in this respect.

Arvada, Colo., Mar. 4.

[I sincerely wish there were a reliable drug cure; and I shall be only too glad if such has been found.]

I believe I never said that carbolic and salicylic acid would not cure; but the former, at least, seemed to do no good in our case. I tried (or, rather, a college friend for me) carbolic acid diluted according to Cheshire. A quantity of this mixture was introduced into test-tubes containing pure cultures (i. e., the growing germs of foul brood in beef-gelatine). Did it kill them? Not at all.

Every one, so far as I know, has been successful with the mere starvation (or foundation and clean hive) plan; but very few by the drug plan; hence I have recommended the former.

I am not opposed to the drugs, and I sincerely hope that the time will come when we all shall be able to use them with satisfaction, because it will be far cheaper. Perhaps you will be interested in the following very readable article from Mr. Gravenhorst: but don't forget to note that he says foul brood will go off many times of itself. If he is correct, and I think he is, it is easy to explain *some* of the drug cures.—ED.]

LYSOL

ITS USE AS A CURE FOR FOUL BROOD: CRUDE CARBOLIC ACID PREFERRED TO THE REFINED.

By C. J. H. Gravenhorst.

Referring to a report from Germany, where a Mr. Fulde has cured foul brood by means of a new disinfectant, lysol, Dr. C. D. Miller asked in GLEANINGS, page 88, "What's lysol? and will it work as well in the English language as in the German?" The editor remarks thereon: "I should be interested, also, in knowing whether the disease stayed away. Perhaps Mr. Gravenhorst will answer the question."

Yes, I will answer the question according to the best information I can get. I have not tried lysol, because I did not know of it before September of last year.

The new disinfectant has been manufactured for a few years by Schülke & Mayr, at Hamburg, Germany. They produced it from coal-tar. It has a brown color, and smells like tar. In Germany it is to be had in every drugstore, and perhaps in America also. Mr. Fulde purchased a bottle of lysol for 2½ cents, and therewith cured his bees, which were badly infected

with foul brood. He took ten pounds of sugar-syrup, boiled and skimmed it, and mixed it up with 24 drops of lysol and 4 drops of carbolic acid. He gave a colony a soup-plate full of this food. After three days he found the sick larvae dry in their cells, and in a lapse of three weeks not a trace of foul brood was to be found in his colonies. They were sound, and did swarm. Later he has fed lysol in the same way, particularly in the spring, to protect his bees against foul brood. He never saw a trace of it again.

That's all I know about lysol. I hope some of the German and American bee-keepers will try the new disinfectant. It would be a great benefit to bee-keeping if lysol should prove to be a remedy for such a rapidly spreading disease as foul brood. Then it would be a trifle for every one to cure the malady himself. However, I confess that I do not have such confidence in lysol as Mr. Fulde has. Experienced bee-keepers in Germany, and I myself, too, are of the opinion that the disease will disappear, oftentimes, without any cure other than a good honey-flow, when good sound honey is coming in, and that most of the remedies tried in such cases did not cure foul brood at all. The good honey-flow only, did it, nothing more. Hundreds of remedies have been recommended, but, when tried, they would not work as was claimed. May be that, in one or the other case, the remedy was not used as it should have been; but I think most of the recommended remedies are worthless, and rest upon illusion.

On account of the importance of the matter, it may not be out of the way to report concerning a disinfectant that I have used nearly twenty years, with such results, that, for my part, I hold the foul brood question as fully solved. I have had to fight hard against foul brood, as I resided in Brunswick, and, later, here in Wilsnack; but I have never lost one colony by it. I had to guard my apiaries against neighboring bees infected with foul brood, in apiaries only a thousand paces, or less than half a mile, distant. Well, it was a very bad position for myself; but I have fought it out. In a few cases, where the neighboring apiaries were lost by foul brood, I have found in some of my hives slight traces of the disease. However, they disappeared swiftly by my treatment. I used, and have used till to-day, although I have not at present any apiaries near by that are infected with foul brood, carbolic acid—not the refined article you get at the drugstore in the shape of white crystals, but black and unrefined carbolic acid, which is intermingled with coal-tar, and mostly used as paint. Refined carbolic acid is too strong, and the sanative power of the tar is absent in it. I am of the opinion that just the tar, in connection with the carbolic acid, has much to do in the cure of foul brood, as Dr. Preuss said. He was the first bee-keeper who studied foul brood. This opinion is confirmed by

another prominent German bee-keeper, Mr. Schroeder, at Frankfort-on-Main, who has mixed up refined carbolic acid half and half with coal tar, and thus cured foul brood. I, however, prefer the unrefined carbolic acid, not this mixture. Although among foul-brood-infected apiaries at Brunswick, I have never lost a colony by this disease; yes, and I have cured the foul-broody apiaries of my neighbors, except one, which was a total loss, as the owner was careless and did not follow my directions. I bought his hives and combs, disinfected them, and used them without harm to my bees. All the bee-keepers who followed my directions strictly, succeeded in getting rid of the disease.

To guard my bees against infection by foul brood, I take $\frac{1}{4}$ gallon rain water, add to it a teaspoonful of unrefined carbolic acid, and stir it. With a brush, dipped in this solution, I wash the bottom-boards every spring, after the first cleansing flight. By doing this I destroy not only the germs of foul brood, but also the eggs of bee-lice and wax-moth which may be there. In badly infected apiaries, I found now and then some traces of foul brood in some of my colonies. Then I applied such a washing every eight days. The steam of this solution disinfected the bees, the food, and the cells. Now and then I examine the brood-combs of a suspicious colony, and when I see that there are many empty cells which I had seen some eight days before filled with eggs or larvæ, I am sure I have before me the first traces of foul brood. The bees, in helping themselves, had borne out the dead larvæ. Then, among the capped brood are to be seen many empty cells. Should I find, besides this, some sunken cells, and, after opening them, that brownish, tough matter in them, I spray such combs besides washing the bottom-boards by means of a "refraicheur," with a warm solution of four or five drops of my carbolic acid to a teacup of water, thoroughly mixed up in a bottle. This does no harm to the open or sealed brood. Besides this treatment I feed now and then such infected colonies with sugar syrup and add to a teacupful of the food three or four drops of my carbolic acid.

Colonies badly infected with foul brood I treat in the following manner: At a time when the bees will build comb I brush them upon starters in clean hives, wash the bottom-boards, and feed the bees with those solutions of food I have mentioned above. I have found out that starters are better than foundations. I give only four or five frames with starters according to the size of the swarm; and later, before the combs are finished; and, further, only foundations. The combs of the colonies I render part in wax and part are disinfected. Out of some of the badly infected colonies I hunt the queen. When all the brood is emerged from the sound cells, I brush also the bees upon starters; or if the bees do not build combs, from want of a honey-flow, upon comb foundation or disinfected

combs. Later in the season, when comb-building is out of the question, I unqueen the colonies and unite the bees, after all brood is emerged, with those I had brushed upon starters. Then the combs are disinfected. This I do in the following manner: At first I uncapped the cells, then I lay one frame after the other in a vessel filled with a solution such as I use for washing—perhaps a little stronger. The comb floats on the solution. Now I take a hand-syringe and squirt the solution with all my force into the cells to fill them, first on one side, then on the other. This is necessary, as otherwise the cells will not be filled to the bottom; the foul-broody matter will not give way, and the solution will not penetrate it. If all cells on both sides are well filled, then I extract the solution by means of an extractor, or by jerking the combs, and then hang them up to dry. After from eight to fourteen days in the open air, when they do not smell any more of carbolic acid, I use them as I would any other good combs.

The infected hives were also washed inward thoroughly with the washing solution, and, after laying two or three weeks in the open air, were used as new ones.

I am so very cautious in this matter that I wash the inside of every hive in the spring, except the new ones, with my disinfectant, before I put in a new colony. I need not say that all the tools used by infected colonies must be disinfected; also, that one must wash his hands after he has had to do with infected bees.

I know, however, that American bee-keepers do not have much confidence in the carbolic-acid cure of foul brood; but it is a question whether they treated their sick colonies with a remedy that is composed of and used in my way.

If it is true, what Fulde says about lysol, and if he is not misled, as are so many others who recommend foul-brood remedies, then lysol will surpass the unrefined carbolic acid as a disinfectant for foul brood, especially as it is employed with less labor and cost. On the other hand, if lysol does not prove to be such a remedy as is claimed, then I will use the unrefined carbolic acid in my way, as I have done till now, which has saved me from any loss by foul brood under dangerous circumstances.

Lysol consists of cresylic acid made soluble in water by a patented process, by means of saponification. It is a powerful disinfectant and antiseptic, and is largely in use in the hospitals of the Old World as a substitute for the less active but highly poisonous carbolic acid. It is further much employed in horticulture, where it has proved, in weak solutions, a very active remedy against vermin and parasites of all kinds. It is manufactured by Schülke & Mayr, Hamburg, and sold by their general agents for the United States, Lehn & Fink, 128 William Street, New York. It is put up in 1-lb. bottles, at 60 cents.

Wilsnack, Germany, March 9, 1895.

BEE-KEEPING IN CUBA.

60,000 LBS. HONEY PER YEAR, AND LOOKING TOWARD A QUARTER OF A MILLION; FOUL BROOD IN CUBA INCURABLE.

By W. W. Somerford.

Mr. Root:—In your footnote, Jan. 15, to Mr. Fred L. Craycraft's letter from Cuba, you say some of your readers would perhaps like to view some pictures of Cuban shed or house apiaries.

No. 1 is a picture of a part of the main shed that covers Mr. A. W. Osburn's 700 hives that

with his record-book of queens, for he believes in keeping up with them closely, and breeding queens only that "give results" in the way of honey-gathering. Hanging from the plate of the shed you will see scores of Miller feeders, which are used to advantage during the rainy season only. His honey-carts you will also see in the main alley between the rows of hives. The eaves of the shed come down so near the ground, and guava-bushes grow up so thick and close, that bees hardly ever sting a person while working under the roof, and are not much inclined to rob. You may ask why the bush-

FIG. 1.—A SHEDDED APIARY IN CUBA; A. W. OSBURN IN THE FOREGROUND.

are all under one roof—twelve miles west of Havana, near the little town of Puntabrava. Fully 17,000 square feet of tile and corrugated iron roofing is required to cover the apiary, one main shed running straight up the hill 300 ft., crossed by two others of about the same length, all opening into or joining the main shed, thus making all conveniently situated up the hill from the honey-house and that big steam honey-extractor.

Mr. Osburn uses a honey-cart that holds 75 or more combs at a time, and it is a downhill pull to his honey-house; so, hauling in his tons of honey is only fun for his son Harry, who is an expert in all the branches of the industry, having been raised from childhood in an apiary, and continually among the bees, for his father has for years been one of the largest honey-producers on the island, or anywhere else, for that matter. His average crop is about 60,000 lbs. annually, which he intends, if honey goes *much lower*, to increase to a "quarter of a million" per annum.

You can, as usual, see Mr. O. at his desk,

es are not cut away. Because they save honey, or the consumption of honey, by keeping the bees quiet during the long hot summer days, which is very essential in hot climates; for hives well shaded will have plenty of stores, while those in the sun will be starving.

Picture No. 2 is an interior view of the Casanova apiary, situated 21 miles east of Havana, and at present in charge of my brother, Fred O. Somerford, who has resided in Cuba over four years, continually among the bees, and has had, I presume, as much experience with foul brood as any one during the past four years, never being without it, scarcely, during the whole time. He, like Mr. Taylor, has concluded that it can be transmitted by foundation made of foul-brood combs.

Mr. A. W. Osburn, who has had varied experiences with the disease in California as well as in Cuba, thinks, like myself, that foul brood in a hot climate, and in large apiaries, is something too progressive for any remedy yet known to the fraternity. I have, after reading all the fossil works on the subject, and experimenting

for three years with various remedies, such as phenol, starvation, melting up all combs, scalding hives, killing queens, caging all queens 21 days to stop breeding for a time, while new combs were being built out, come to the conclusion that a new and more effectual remedy will have to come along before much foul brood in the tropics is eradicated except by total annihilation, which surely follows if the disease is not checked each year by melting all combs and putting the bees on new foundation.

I have lost 250 colonies by the disease—worth in Cuba not less than \$1000, and all my neigh-

never uses German script, but plain English letters, so his writing is read as easily as the printed page. But here's his letter, which loses by the translation:

My experience agrees with yours in the matters you mention, except the case in which you saw a queen kill a worker. To balance that, I once had a young queen sting me, which I had taken out of an after-swarm, and held in my closed hand. The sting did not remain in the flesh, and it was less painful than that of a worker. Since then I have had in my hand thousands of queens young and old, but have never again been stung by one.

bors around have shared my fate, or their bees have.

Navasota, Tex. (at present).

BEE-KEEPERS' ASSOCIATIONS IN GERMANY.

WHY THEIR MEMBERSHIPS ARE SO LARGE.

By Dr. C. C. Miller.

I have a letter which I esteem very highly, not only because it clears up a matter concerning which I have for a long time been curious—the reason why the Germans have such large bee-conventions—but also because it comes from one whom I am proud to number among my friends, the able editor of the *Deutsche Illustrierte Bienenzeitung* (German Illustrated Bee Journal), who is already well known to the readers of GLEANINGS through his contributions to its pages. I wish I could show to all of you his writing. Although past his threescore and ten, the address on the envelope would easily be taken for copper-plate. Although his letters are in the German language, in pity for my lack of familiarity therewith he

I have read in GLEANINGS for January 1 your statement concerning the number of members of the German Central Association, as also the remark of Ernest Root. Now I will impart to you the secret why it happens that the Centralverein (Central Association) has such a large membership, and if you wish you can betray the secret to Ernest.

In thickly populated Germany there are ministers and teachers who form about them little Vereine (societies or associations) whose members generally meet monthly or quarterly. Every one who has bees, even if only a couple of colonies, allows himself to be enrolled, without attending each meeting that is appointed. These small Vereine obtain at a very low price one of the reasonable bee-journals, as the *Centralblatt* or *Leipziger Bienenzeitung* for 1 mark (25c), or 65 pfennig (about 13c) a year. Many of these small Vereine have their own bee-journals, which then cost more, but never more than 50 cents. These small Vereine (Special-Vereine) are united to the Centralvereine of the different provinces or small states. For example, in Mark, my province of the kingdom of Prussia, the Markische Centralverein consists of 77 Specialvereine, with 1539 members, who, in the fall of 1894, put into winter quarters 15,000 colonies.

Now comes, however, the principal thing, which

explains all. All the Centralvereine receive a grant or allowance from the government yearly, and all the members share alike in this grant. Whoever is not in a Verein has no share in the money which the government grants yearly. Many of the Centralvereine receive so large an allowance that they deliver to their members one or more bee-journals free.

At the large conventions, where all the Centralvereine come together, extra money comes from the government, and even from private sources, from which premiums are offered, transportation paid or objects for exhibition, and often free railway passage, as well as payment for articles damaged or lost in transit. In Vienna, at the convention which I reported in GLEANINGS, it went even so far that the members had their common meals, including wine, free. "There's the rub," says Hamlet! Whoever is not a member of a Verein must wipe his mouth—that is, he gets nothing of all this.

I once traveled to a convention of this kind with a man who admitted that he no longer kept bees, but had himself enrolled in a Verein, and paid his dues of 30 cents, for which he received the bee-journal and the opportunity of visiting strange places. In our deliberations at Kiel he took no part, but probably in all the favors, visit to the museum, man-of-war, etc.

Yes, friend Miller, you must set all sail to procure such a cement in your States, which will not only secure many members, but also hold them together.

Freundlich gruessend,

C. J. H. GRAVENHORST.

For one, I feel like giving a vote of thanks for this information. Just the thing we needed. Now, can any thing of the kind be done in this country? The answer has always been that distances are too great and bee-keepers too scattered. Right there is the rock on which we have always split, depending for membership solely on those who could attend the meeting. You will readily see that not all the members attend the German conventions; but the inducements are sufficient to make a man keep up his membership, even if he never attended a single meeting. So while our great distances may count against the largest attendance at conventions, it counts for nothing whatever against a large membership.

The only thing needed, then, to bring us up on a level with Germany, and, for that matter, with Canada, is to get the grant from the public treasury. I think I hear some one say, "Oh! there's no use. We can't get any thing of the kind." How do you know we can't? I feel quite sanguine that there's just as much enterprise here as abroad; and if we go at it in the right way we can get all the help we need. Indeed, something has already been done. The bee-keepers of Illinois succeeded in getting, at least for one year, an appropriation of \$500. It was given to the State society, with the express stipulation that it should be used to spread information—in other words, to publish their report. Good was done by it; but it had very little effect in the direction of increasing membership. Probably a large number had

the benefit of the reports who were never members of the society, and, under existing circumstances, never will be. With a large membership it would be much easier to get an appropriation from the State legislature.

Now, suppose the Illinois society receives another grant of \$500; how would it do for them to profit by the example of their foreign brethren? I think it could be so managed as to make the society five or ten times as large, and still keep within the restriction that the money must be used for spreading information. Let's figure. Suppose the society make arrangements to furnish free to its members a bee-journal, and on any one of them it could probably get special rates so that, at the highest, it would pay not more than 80 cents per copy, the journal publishing in full the society's report. Now, suppose the membership-fee be placed at 25 or 50 cents. Does any one doubt that a large number would be induced to join who are not now members, and many who now take no bee-paper would do so by paying to the society less than the regular subscription price of the paper, without saying any thing about the privilege of membership? Let's see how the thing would come out, if the annual fee be placed at 25 cents. Allow \$50 to be reserved for expenses, and we have \$450 left. Each member pays in 25 cents, and the society takes that, and 55 cents more, to make out the 80 cents it must pay for his paper. It seems clear that the society can afford to do that just as many times as 55 cents is contained in the \$450. If I figure straight, that would make 818 members. Could not get 818? Well, then it could reduce the fee, making it only 10 cents per member, and take in 642 members. There's a power in numbers, and I believe the thing to work for lies in that direction. The fact that such a thing is done in one State will give strong leverage to work upon the legislature of another State. Don't you believe that, if bee-keepers push as they might, in a few years there might be large societies in each State?

Marengo, Ill.

[We are always glad to get anything from the pen of that practical German bee-keeper and bee-writer, C. J. H. Gravenhorst. If our readers do not know him through his own most excellent journal, they surely do know him to some extent from his writings in our journal.]

On account of the magnificent (geographical) distances, I am afraid, as you suggest, we shall never be able to see a complete realization of such a plan as is now in vogue in Germany. Our country is made of so many little countries, and so much has to be done through State appropriations, that it is very difficult to get any thing from the national government to help all bee-keepers alike. Instead of concentrating any great effort on any particular State, I should be more in favor of getting an appropriation, if times ever do get better, from the powers that be, at Washington. A State association, no matter how flourishing, would never be more than a State organization.—ED.]

EARLY SWARMS.

Question.—I am desirous of securing early swarms. Would there be a gain or loss along this line by putting on surplus cases of sections?

Answer.—It might be safe to say that, taking early swarms into consideration, there would be a disadvantage or tendency toward a few days' delay, if the surplus arrangement is put upon the hive before the bees swarm. Heat is one of the elements in forcing early swarms; hence, by putting on the surplus arrangement before the hive is crowded with bees, much of the heat from the colony will be distributed up among the sections, which would retard swarming, as it also does brood-rearing. If early swarms are what we *must* have, even if we have to sacrifice other values, then it is best to keep the top of the hive as close as possible, and stimulate the bees by feeding them or otherwise. Later on, when the hive becomes crowded with bees, and preparations for swarming begun, the placing-on of sections may not delay it. But if we count surplus honey a gain, then I can conceive where there would be a gain in putting on sections as soon as our main honey-harvest opened, as it is often the case that, with all our crowding and desiring early swarms, the bees will obstinately refuse to swarm, when we not only fail to accomplish what we are after, but lose a part or all of the honey crop we might have had if we had put on the sections at the proper time. I verily believe, that, during the past, when conducting experiments along this line, I have sustained more loss by trying to force swarms by crowding the bees than by giving them too much room. Hence my advice of late years has been to place the sections on the hives at the proper time, no matter whether swarming is desired or otherwise, resting assured that, with the majority of bee-keepers, more swarms will issue, when doing our best to secure a good crop of section honey, than we could expect under any conditions, and fully enough to satisfy any reasonable person.

WHEN TO PUT ON SECTIONS.

Question.—When is the proper time to put on sections for surplus?

Answer.—No set time as to month or day can be given for putting on sections in any locality, as all depends on the strength of colony and the time of the opening of the blossoms which give us our main honey crop, both of which are advanced or retarded in accord with the earliness or lateness of the season. Some say, put on all surplus arrangements as soon as the first buds giving our surplus honey are about bursting open, no matter about the strength of the colo-

nies. Others tell us to put on sections as soon as the colonies are strong enough, without any reference to the time of the blooming of the flowers, they saying, "It is a mistake to put off putting on sections till the honey harvest is upon the bees, as they will sometimes waste time looking through the surplus apartment before going to work." I can not agree with either of the above, as it savors too much of the old "luck in bee-keeping" we used to hear so much about, and does not give credit to any apiarist of managing his business intelligently. After years of experimenting, to know just when the sections should be placed upon the hive, I have arrived at this: Wait about putting the sections on till the hive becomes populous with bees and the combs well filled with brood, and till the bees are securing enough honey from the fields to begin to lengthen the cells along the tops of the combs next the top-bars of the frames, or build little bits of comb here and there about the hive. When we see this it is time to put on the sections; for if we delay longer we are sure to lose in time and honey; while if we place sections on the hive, no matter how populous with bees it may be, before any honey is coming in from the fields, we shall lose by the bees gnawing or tearing down more or less of the foundation placed in the sections. If we use only starters of natural comb in our sections, then they can be placed on the hive as soon as the colonies are strong in bees and brood, if we so desire; but even then I can see nothing gained over the other, unless we are liable to be crowded for time at the *right* time for putting them on. If my memory serves me rightly, Dr. Miller has put forth the claim that it is only after the honey season is over that the bees gnaw holes in and tear down foundation, which may be correct with him in his locality; but with me bees always mutilate foundation in the sections, more or less, at any time of the year when an abundance of numbers, or hot weather, crowds them into the sections at a time when there is no honey coming in. I had scores of sections one season in which all the upper half of the foundation was gnawed away but a little strip or neck about $\frac{3}{8}$ to $\frac{1}{2}$ of an inch in width; and when honey began to come in, and the foundation was worked out, it twisted and turned to such an extent that it was attached to the separators on either side, thus spoiling such sections for market when they came to be removed, as the honey would be set to running in getting the combs loose from the sections.

WHEN TO PUT ON SECTIONS ON NEW SWARMS.

Question.—When is it best to put on sections on a hive having a new swarm?

Answer.—That will depend somewhat on how you work. If your swarm is large, and you have full sheets of foundation in the brood-frames, it is well to place a case of sections (and they should also be filled with foundation)

right on the hive when the swarm is run in; but should you fill the sections with foundation, and use only starters in the brood-frames the queen would be likely to go into the sections to deposit her first eggs unless a queen-excluder were used, in which case she could not get into the sections, no matter how the hive was arranged below. With nothing but starters in the brood-frames, and no queen-excluder used, then it is best to wait about putting on sections till the queen has commenced laying in the new comb built below, when the sections can be put on without fear of brood in them. The plan I consider the best, and the one I use more largely than any other, is, to contract the brood-chamber to two-thirds its usual size, using only frames having starters in them of foundation about half an inch wide, on top of which is placed a queen-excluding honey-board. The new hive thus prepared is set on the stand of the parent colony while the swarm is out, and the sections from the removed hive placed over the queen-excluder on the new, when the swarm is hived in this new hive on the old stand, when the old or parent colony is placed at some distance away on a new stand which we wish it to occupy. In this way work does not stop in the sections at all, and we, as a rule, get the frames in the contracted brood-chamber filled with nice straight worker combs, at a less cost to us than the purchasing of foundation and fitting it into wired frames.

THE DIVISIBLE-BROOD-CHAMBER HIVE.

THE PRINCIPLES OF THE HEDDON HIVE SET FORTH BY AN ADMIRER OF HIS SYSTEM.

By Honey Producer.

In all the arts with which we have to do, there are certain governing principles or laws peculiar to each, with which we have to comply if we wish to accomplish a certain definite result; and, reasoning at least from analogy, honey-production and hive-construction should be, and are, no exception to the rule. However, as with the farmer, so also with the bee-keeper, there are climatic and other conditions or principles over which he has no control, and which affect the obtaining of the object he has in view, thus giving varying results, no matter how correctly and effectively he has applied those which he can control.

The honey-producer applies the principles of his art largely through his hive, which fact shows its important relation to the cost of his product. Like other producers, his first object

is to obtain his product at the least cost possible. Where this is accomplished, his hive will be so constructed, and its manipulation such that he applies the principles of his art to each individual colony, 1, with the greatest effectiveness; and, 2, with the least expenditure of labor. However, be our hive construction and manipulation never so good, we can not force the productiveness of any colony beyond the limit of its ability, nor, on the other hand, lessen the labor of manipulation beyond the point of profitable effectiveness. We see, therefore, that, in order to be the most effective, these two elements must be made as weighty as possible, and so adjusted in our hive that it will exactly balance upon its fulcrum, honey-production.

It must also be remembered that the natural principles which govern the development of the honey gathering and storing instinct of our bees can not be changed, but that the methods of applying them can, and that they either hinder or help the effectiveness of these principles. That the sectional hive and system, from which we can not with justice separate the name of James Heddon, its inventor and patentee, requires, in practically applying principles, the least known amount of labor, does not seem to have been generally disputed, except by some who, for some cause, have been troubled with brace-combs between the sections; but that it is also pre-eminently adapted to the *most effective* application of these same principles to the colony it contains, and hence to the securing of the *greatest* amount of honey from each individual colony, is ignored by a few, disputed by some, doubted by others, and entirely overlooked by many.

The cut is a good representation of this hive. *A* is the stand, *K* the loose bottom-board and two loose entrance-blocks; *B* and *H* are shallow brood-cases, one or more of which are used for a brood-chamber. Each is of five Langstroth-frame comb capacity, and contains eight shallow combs in close-fitting end-frames, which

also closely fit their case endwise, and are supported on tin rests, and held tightly together and securely in position by a thumbscrew at either end, which arrangement allows the cases to be handled in any position as one solid whole, and yet, by loosening the thumbscrews, it leaves the frames readily removable. *M* should be the queen and brace-comb excluder, but is not shown and is generally wrongly named "honey-board." *D* and *E* are wide-frame surplus-cases for comb honey. These have the same kind of frame adjustment as the brood-cases which are used for surplus-cases when extracted honey is wanted. *F* is the cover. Besides, there is the escape and board which are not shown, and without which the hive is incomplete, although not a part of the invention. Each brood-case, outside measure, is $19\frac{1}{8}$ inches long, by 13 inches wide, and $5\frac{1}{16}$ inches deep. The wide-frame surplus-cases are the same length and breadth, but only $5\frac{1}{16}$ inches deep. Considering, now, the size, shape, lightness, and construction of the parts, you will see how admirably adapted it is to its system of case (sometimes called hive) manipulation, no matter whether of the brood or surplus apartments, or these as used in connection with each other or any of the other parts of the hive, or of the hive as a whole, and for which it is intended and expressly built.

When left to themselves, and under natural conditions, bees will store a little of their honey about the sides of their brood-nest; but the great bulk of it will be above. Besides, they store it as near the top of their hive as possible, and for consumption use that lowest down and nearest the brood. In breeding, the upper part of the brood-nest is kept immediately next to the honey. When the upper brood hatches, and the honey-flow is sufficient, the bees will fill with honey the cells out of which it hatched, thus continually working to connect the brood and honey by filling with honey the *shallow* space continually being created between them. From these natural conditions we learn some important principles as they relate to a hive's construction and its manipulation.

1. That surplus cases should be added above the brood-nest, and hence our hives built for top storage.

2. That we should not compel our bees to travel over honey at the top of the brood-nest in order to store their honey, and hence the division between the surplus-apartment of our hives and the brood-chamber should come right where the brood and honey meet. In other words, the construction of our hives, and management, should be such that there will be no honey, or as little as practicable, at the top of the brood-chamber when we wish the bees to store in the surplus-cases above it.

3. That brood should extend under the whole bottom surface of the surplus-cases; hence surplus-cases should not extend endwise or side-wise beyond the brood-chamber; neither should

there be combs of honey beneath them, at the sides of the brood-chamber. It is a fact, that a brood-chamber of sufficient capacity, and more than eight combs wide, is quite liable to have its outside combs filled with honey; hence a brood-chamber should not be more than eight combs wide.

4. From principles two and three, we see that any hive or system which attempts to fill the brood-chamber with honey for winter stores, either before or while the honey-harvest is on, does so at the expense of important conditions necessary to the development of the strongest honey gathering and storing instinct of the bees.

5. That when one or more surplus-cases have been filled sufficiently to justify the addition of another, it should be placed right between the brood and honey already stored, and, as might also be inferred, and which experiment proves true, the shallower the opening which we make for storage between the brood and the honey already stored, the stronger the instinct of the bees to fill it. It is also much better that the first surplus-case which is put on be shallow rather than deep, and of large capacity.

6. A little reflection shows, and experience proves it true, that the deeper the brood-chamber the greater the liability to have honey stored at the top of it by the bees, which they will have to traverse to store honey in the surplus-cases, greatly lessening their energy.

7. A little mathematical calculation shows, too, that, the deeper the brood-chamber, the less surface there can be above it for top storage, and hence the deeper will the surplus-cases have to be in order to have sufficient capacity, in adding which the deeper will be the opening made between the brood and honey, thereby again lessening the instinct of our bees to fill this space *promptly*.

8. It is a fact that, when a brood-chamber is larger than a queen can keep filled with brood, the remaining space will be filled with honey. We at once see, therefore, that such is a mistake, where we wish a brood-chamber filled with brood, and devoid of honey.

You will now look at the cut, carefully study the hive, its shape, construction, and size of the different parts, and connect therewith the following manipulation, and carefully compare any and all of its bearings with the above principles.

Suppose our colonies are in normal condition, and ready for the surplus-cases at the opening of the summer honey-flow. When we put on the first case we will interchange the two brood-cases—that is, place the upper one below and the lower one above, and then put on the honey-board and surplus-case. When this *shallow* case is sufficiently filled, we will add another on top of the honey-board and beneath it, and so on with others as required upon the tiering-up plan. You will notice now, 1, that the brood-nest is flat on top instead of rounding;

2, the brood extends to the very top of the brood-chamber; 3, that the brood-nest was divided where it was largest across, and thereby the brood was, so to speak, spread out underneath the surplus-cases; 4, that placing the honey where the bees want brood, induces them to remove it and put brood in its place, thus filling the brood-chamber with brood; 5, that, in adding surplus-cases, we continually create a shallow opening between the brood and honey stored.

The swarms we hive in one brood-case; place them upon the stand of the parent colony, and give them the unfinished surplus from the same, and add an empty case, if needed. From this arrangement of the hive, you will notice the following conditions which now exist: 1, the brood-chamber will be filled with brood, because of its small capacity; 2, brood will extend to the top bars, because of its shallowness; 3, when filled with brood, it will extend under the whole bottom surface of the surplus-cases; 4, the whole body or bulk of the brood is nearer to the surplus-cases than it can be brought by any method of narrowing the brood-chamber to contract it; and, also, the bees are in a more compact form to work; 5, that a shallow opening between the honey stored and the brood-chamber is established for storage.

In my opinion, with no other hive or system that I know of can all the principles of honey-production, as mentioned, be so easily and perfectly applied to our colonies, either before or after swarming. "But," says some one, "there are other things to be taken into consideration if we are to be successful." True; but can the most indulgent of editors be expected to permit the space?

Just as I finished this article, GLEANINGS came to hand; and you may guess of my surprise upon finding another claiming nearly all of the essential features of Mr. Heddon's hive and system. However, it is a pretty late day to succeed in this kind of work.

[As there are some who think the divisible-brood-chamber hive is the coming system, I have asked one of them (a user of the Heddon, and one who thinks there is nothing like it) to write it up for the Trade Notes department, and this he has done in the foregoing. Along in the same mail came, unsolicited, an article from Ezra G. Smith, also an admirer of the Heddon hive. He writes of it as follows:]

I want to say something about Heddon's hive. You say in GLEANINGS, Mar. 15, that two-story Langstroth hives were used years ago. That is so; they were used, but not as divisible brood-chambers. We had no way to restrict the queen. It was intended and advertised, sold, and used as a single-brood-chamber hive. When the queen went above, it was not because we wanted her to do that, but because we could not help it. I have used the Quinby, Langstroth (Hoffman frame) hives; have used the Heddon hive five or six years; and if I

had to go back to the other hive I would quit the business. I can take care of my bees with one-half the work that I formerly had to lay out on them. I think the Heddon hive is as much ahead of the other hives as those hives are ahead of the old box hive.

EZRA G. SMITH.

Manchester, N. Y., Mar. 19.

[I shall endeavor, so far as it is possible, to make the Trade Notes department represent fairly the views of our subscribers along the line of practical bee-hive construction. While I understand that there are some who like the Heddon system, I am also told that there are others who have tried it and abandoned it. Now let us hear from these latter, and wherein the multiple chamber is not a success.

I am not seeking this information pro and con because we desire, or may desire, to go into the extensive manufacture of Heddon's hive under royalty, but only to get at the truth. It is true we did write to Mr. Heddon, asking royalty price per hive; but it was only that we might be in a position to supply such hives, in a limited way, when ordered, and not that we considered it the best hive, as Mr. Heddon seems to think. At present we are satisfied with what is common property, viz., the Langstroth system. On the other hand, we shall endeavor to hold ourselves open to intelligent conviction.—ED.]

CATNIP HONEY, A BARREL OR MORE.

In 1892 one extracting, of 500 to 700 lbs., was either pure catnip or else so strongly impregnated with that flavor that no other could be detected. Besides, I could not find that they were working on anything else in particular at the time. Once or twice before when I had not many bees I secured some. But that year the bees fairly swarmed on it, as they sometimes do on basswood.

Sang Run, Md., Feb. 25. C. A. MONTAGUE.

PROPOLIS DEPOSITED IN A LIQUID STATE.

Before the introduction of the movable frame I used the Miner cross-bar hive. A piece of thin cotton cloth was spread over the bars when a swarm was hived, to prevent the bees from attaching their combs to the loose cover between them. This was allowed to remain two or three days, and then removed. On removal it was generally found to be almost or quite saturated with liquid propolis, and was as limp as if wet with water. This and some other circumstances have led me to believe that bees use propolis in only the liquid form. Indeed, it is difficult to conceive how they can handle it in a semi-solid state. I have often seen them loading their pollen-baskets with the solid material; but I think they liquefy it before using it. With this liquid they varnish their combs, and all other surfaces within their hives, and wherever else they may cluster.

That motion called "raking," so puzzling to many of us, is, I think, simply a part of their manner of during this job. A. S. MARTIN.
Roanoke, Va., March 4.

[It can scarcely be doubted that propolis is put on in a liquid, or partly liquid, state. The bees secrete some sort of fluid that seems to cut it enough to render it plastic and liquid. I can hardly think that the "raking motion" has anything to do with propolis. The motion is witnessed only at the entrances; at least, I do not remember to have seen it elsewhere. At all events, there is no sign of propolis where they have been raking; but I do find particles of paint removed.—ED.]

GOOD WINTERING SO FAR.

I have been much pleased to-day, Feb. 19. As I was sitting in the office a hen cackled in the workshop, and I opened the back door to see what was the matter. The sound that struck my ears caused an alarm. I thought robbers were at work in the apiary, and hurried out. A glad surprise met me. It seemed that all the bees from every hive were in the air giving one glad hallelujah for a free foot, or, rather, a free wing. I went to the hives, and pulled away the blocks which some of them had in front, and they had a general house-cleaning. I think there were not more than 100 or 150 dead bees thrown out of each hive, notwithstanding the severe zero weather and the snow 15 or 18 inches deep for the last three or four weeks. They were in single-walled Dovetailed hives, without a particle of protection; for if they can not live in such hives through our winters, only 6 below zero, I want to know it before I get any deeper in the business.

Port Norris, N. J., Feb. 19. J. R. PRICHARD.

DANGER IN SULPHURING COMB HONEY; A BED-BUG STORY.

I should like to caution beginners in the bee-business about using sulphur smoke on comb honey to destroy miller-worms, as directed by Mr. Doolittle. Last fall I sold my honey to Byron Walker, of Evart, Mich. He directed me (after grading up the honey) to burn sulphur in the room; to cork it up around the windows, and burn a pound of it. Inclosed I will send you a piece of wood showing what sulphur smoke will do. I had to put more than 100 lbs., out of 1400 lbs., that Mr. W. had graded A, into grade B; and some of grade B was not fit to send to market at all—not that Mr. Walker would not have been obliged to take it, but I could not afford to sign my name to it. After I wrote him about it he said he had tried burning sulphur on old comb only, but got his authority from Mr. Doolittle. By the way, Mr. Walker buys a very large amount of honey every fall. He is a square man to deal with. His own honey amounted to about 22,000 lbs., counting in what he got from one apiary that he has in Wisconsin. Now, I am very much interested in Mr. Doolittle's writings, and have

gained some very valuable pointers from his writings, and believe he is one of the safest guides in the United States.

Mt. Pleasant, Mich.

H. S. WHEELER.

[The sample of wood sent is considerably discolored on one end. I think Doolittle is all right, and that the trouble was in your giving the honey too much sulphuring. Too long a sulphuring will turn every thing yellow, as I happen to know. Let me give an illustration: Years ago, when I slept in the shop as a sort of "night watch," I discovered, much to my dismay and sorrow one morning, that bedbugs—yes, real live crawling ones—had gotten into our little room. Now, you know I couldn't stand that, so I sulphured the room a little, including its contents. But it didn't kill 'em. "Next time I'll kill 'em sure," I said, and accordingly built up a big sulphur fire in a large kettle, and shut the room up tight for three or four hours. Did it kill the bugs? Indeed it did, and, more than that, the side walls of the room were covered with a yellow sulphur deposit; in fact, every thing was covered. There! don't tell any one I've slept with bedbugs.—ED.]

THE FOOD SUPPLY OF FLORIDA.

This is the fourth winter that I have spent in Florida, and I've watched with much interest to see where the food-supply of the inhabitants came from. In mingling with them on sailing excursions I took note of their lunches, and I invariably discovered food obtained from the stores. I can speak intelligently of only this portion of the State. Plums, peaches, pears, mulberries, dewberries, nectarines, and scuppernon grapes grow in great profusion. Christmas day, oranges and lemons amid the green leaves were a thing of beauty; but now, not a green leaf decorates the trees. This is a new town, settled by Northern people, and fruit-trees are too small to bear much.

In the issue of GLEANINGS for Feb. 15, there is a good representation of the head of saw-palmetto, under the large letters "red cabbage-palmetto." In looking at it I wondered where the head of cabbage was, and I failed to discover it. I think what is said of the edible part is rather misleading. I've questioned many persons who have lived among it all their lives, and they tell me that the cabbage is the bud; and in order to make it palatable it must be parboiled to remove the bitter. I would obtain one of these cabbage-head if I did not consider it sacrilege to destroy one of these noble trees to obtain a bud of about the size of my fist, which would require a great stretch of imagination to think was cabbage, which can be raised in a short time, of much finer quality. If I'm not mistaken, the name is not derived from this bud, but from the imbrication of the leaves. If you look at the trunk of one of these trees you will see the bark imbricated, overlapping each other like the leaves of cabbage.

Most of the native women know how to make palmetto hats. They take the center leaf while it is folded together, before it spreads

out, and it does not harm the tree. These hats are very comfortable and durable.

Palmetto logs are used for building piers, as they resist the ravages of time and corroding worms more than other wood.

St. Andrew's Bay, Fla. MRS. L. HARRISON.

SIXTEEN extra pages this time, instead of eight.

ADVERTISERS who see fit to patronize us now ought to get good returns. We shall be publishing, from now on, until the early part of summer, extra editions. The present issue reaches 15,000 copies, and it appears evident that we shall have to print extra copies, for a time at least, to keep pace with the demand.

In speaking of winter losses in his vicinity, Mr. H. R. Boardman, of East Townsend, O., at the end of a letter, writes:

Of all those in my vicinity who have kept bees, and have taken no bee-papers, I can not think of one who has not failed; while those who have taken a journal have nearly all succeeded. I think this needs no comment.

H. R. BOARDMAN.

East Townsend, O., March 27.

WE are giving our readers now a very large amount of reading-matter—perhaps more than many of them will be able to cover; but I appreciate the fact that what may be interesting to one may not be to another, and I try, therefore, to give a wide range in apicultural lore. I am sorry that so many unused manuscripts are now on hand to which I fear I shall never be able to give a place in our columns; but I am striving earnestly to give you the very best we have, properly seasoned and dished up.

A VERY tall compliment was paid us by Mr. D. M. McGaffick, who gave us a call, also of the United States mail service, from Pittsburg to Chicago. Said he, "Of the tons and tons of mail matter that I handle, that which comes from the Home of the Honey-bees is the nicest."

"Why?" said I.

"Because your packages are always nicely wrapped, and the *county* is invariably supplied. If manufacturers only appreciated the importance of this one item they would greatly facilitate the delivery of their mail matter." Here is a point for our subscribers.

THE question is asked in the *American Bee Journal*, "Question-box" department, whether it is advisable to spread brood. Of the 23 who answer, all advise against it excepting Mrs.

Atchley, who speaks for it. For her locality—the extreme southern point of Texas—there is no danger; but experience seems to show that, when practiced in the spring, usually more harm is done than good. If the experts are shy of it, the beginner had better let it entirely alone. I have spread brood, however, in early summer, with great advantage; for I was after increase with a vengeance, and got it. I increased some fifteen colonies, fair to middling, up to 80 good ones, by the first of September. Of course, to do this I had also to divide.

MR. S. E. CORWIN, of Sarasota, Fla., seeing the recent article on candied honey, forwarded the following that he received from one of his old customers who, it appears, purchased honey of him seven or eight years ago:

Friend Corwin:—Do you remember the case of honey you sent up here while my father was sick, some seven or eight years ago? Well, I have three or four bottles of it now. I opened one night before last, and it was apparently just as good as when first received, and not at all candied.

Fall River, Mass.

CHAS. B. LUTHER.

I have long known that honey would keep almost indefinitely; but it is very seldom indeed—in fact, I do not remember to have seen an instance before—that pure honey had kept as long as this without candying. Can any of our subscribers trot out a better?

ADULTERATED FOUNDATION.

A FEW weeks ago we sent to Mr. O. O. Poppleton, of Potsdam, Fla., some small pieces of adulterated foundation, half ceresin and half beeswax. The amount was so small we were afraid that perhaps the experiment might not be satisfactory; but we had only a little of the ceresin wax on hand. Here is what he writes:

I mail you to-day those three pieces of foundation from adulterated wax you sent me to have drawn out by the bees. I don't think it will take more than a glance to show you that it's "no good." Had it shown no stretching when used in such small pieces, I should not have considered that an adequate test had been made of its value when used in full sheets; but if such small pieces will stretch, what would full sheets do? You will observe the sample of thick foundation has stretched less than the medium, and the medium less than the thin; but all entirely too much.

I suppose my extreme southern location, and our having a usually steady flow of honey all winter and spring makes it easier for us here to make any such experiments as this has been than almost anywhere else in the United States.

Potsdam, Fla., Mar. 27.

O. O. POPPLETON.

WE hope to get a larger quantity, and have the experiment tried by different bee-keepers—not that we have any desire to put such an article on the market, but only to prove more conclusively what our early experiments years ago seemed to demonstrate; viz., that pure beeswax gives altogether the best results in the

way of foundation. How any one can be satisfied with a half-and-half mixture, even at a reduced price, is beyond our comprehension.

THERE is talk in the *American Bee Journal* of reorganizing the old Northwestern Bee-keepers' Association. The old organization was a power for good, and would never have disbanded except that it was deemed advisable to concentrate its energy in the State association, having an annual appropriation of \$500.

FOUL-BROOD INSPECTOR WM. McEVoy, it appears, has done some pretty thorough work in eradicating foul brood in Ontario. If he continues in office (as we hope he will) the disease will soon be a thing of the past for Canada. Every State on this side should have at least a foul-brood law. While it is improbable that we should be able to get a State appropriation to defray the expense of an inspector, we should have the law, so that it may be used in case of emergency.

In our next issue, Trade Notes, Mr. Heddon and Mr. Danzenbaker will discuss further, in a friendly way, the patentability of divisible brood-chambers. Some interesting points will be brought out on the subject of patents in general, by both parties. I do not know to what extent this question will be interesting to our general readers; but unless they signify a general desire to have the subject continued, I believe it would be better to have it dropped with our May 1st number. As I have already said, we desire both parties to have a fair hearing. If they wish to continue it further, they can probably do so through the medium of Mr. Heddon's paper.

THE time has now arrived when we should be gathering our usual annual honey statistics, or, rather, statistics of winter losses. We desire every bee-keeper who will, upon receipt of this number, to send us, on a postal card, answers to these two questions: 1. What per cent of your own bees were lost during the past winter, up to the time of your writing? 2. What per cent were lost in your vicinity? In order to get the facts in time for our May 15th issue, it is absolutely necessary that you give this your attention at once. The more distant States, such as California and the like, do not have the winter problem to contend with; but we think the most of the others will be able to report so we can get something of an idea as to how bees wintered, by our May 1st issue. Do not pass the matter over, thinking somebody else will do it for you. We need reports from every one.

In another column, H. R. Boardman writes that he put out his bees on the 5th, from his bee-house, and reports "no loss, and condition perfect." I should like to know, just for the fun of it, whether he would winter as well in

Langstroth hives. If he will procure, say, a dozen colonies in such hives, with loose bottoms, we will pay the expense of transferring to his own hives if they do not winter as well. This is not a challenge to Mr. Boardman; but it might help to throw light upon a point concerning which there has been more or less guessing. For the present I can only say that, with his square and deep hives, he seems to winter better than his neighbors with the Langstroth. In fact, he appears to be the only man, so far as I know, who winters year after year with no loss. Years ago we gave a picture of "the man who never loses bees," and that was none other than our East Townsend friend.

WINTER losses throughout the country, so far as I can gather from the reports, will not be nearly as bad as I at one time feared. The heaviest losses seem to be among the careless bee-keepers—those who have a fashion of letting the bees take care of themselves, largely, or among those who, as Mr. Boardman himself says elsewhere, do not take any bee-paper. Our colonies at the basswood yard, all in one-story chaff hives or winter cases, wintered perfectly, so far as I could see when I went down a few days ago. A large part of their stores was sealed basswood honey that had been kept in combs stored away in stacked-up hives. Late in the fall these combs were distributed in some of the more needy colonies. In addition, we fed very little sugar syrup. Our home-yard loss will aggregate more than I stated in our last issue, from the fact that I supposed we had more colonies than we actually had. The corrected per cent of loss is 4.

DEAD-AIR SPACE HERMETICALLY SEALED, VS. PACKING-MATERIAL.

THE following short editorial is from the *Bee-keepers' Review*:

"Dead air is all right, providing you can get it in a space or compartment that is air-tight," so reads a sentence in an editorial in a late issue of GLEANINGS. I beg to differ. It makes no difference, if the space is between two walls that are hermetically sealed, if these walls are placed between two different temperatures, the air next the wall on the warm side will become warmed and will rise, while the air next the cool wall will become cooled and will settle; thus there will be a circulation inside of even an hermetically sealed space, that continually robs the warm wall of its heat and passes it over to the cold wall. The filling of this space with sawdust or chaff breaks up this circulation.

When I first read it over I was inclined to think Mr. Hutchinson was right and I wrong. Then it occurred that I had read recently in one of the mechanical journals that a steam-pipe incased tightly in wood, leaving an air-space of one to two inches around the pipe, was a better protector than a similar pipe similarly incased in wood, with packing-material occupying the air-space. I am sorry that I can not now refer to the authority; but a long series of

figures by the government inspector was produced to show this. And here is another illustration that means a good deal: Years ago the cylinders around steam-engines of the highest grades contained a casing of wood; and between the casing and the cylinder proper, packing-material; but latterly it has been found that a casing of either iron or wood, leaving a dead-air space of two or three inches, without any packing, gives the best results—that is, the least condensation. The point is right here: Packing-material itself becomes, to a greater or less extent, a conveyor of heat or cold. The better the material, the less it conveys. But the best non-conductor of all seems to be air, pure and simple. If this is correct, my original proposition is all right, friend H.; but dead air space in hive-construction is impracticable and out of the question, and we therefore have to resort to packing. It is true, you may say steam-pipes are usually covered with pipe-covering or plaster; but it is not always found practicable to make a wooden casing around a pipe air-tight; and, moreover, insurance companies do not recommend it. But my proposition was for a space hermetically sealed.

SHALL FOUNDATION BE EXCLUDED FROM THE MAILS?

As our readers know, we have for many years sent small quantities of comb foundation by mail to all parts of the United States, and there has never been any question till recently but that such matter was permissible in the mails. On the 15th of last March, Route Agent C. M. Cotterman, of the United States mail service, came across a package of foundation from us that, it seems, had come in contact with, or at least very near to, a coil of steam-pipe, and melted, leaving, as he said, little but the wrapper. In his opinion, this was not a proper subject to send through the mails, and so reported to headquarters. The matter was referred to our local postmaster, and by him to us. On the 25th of March we dictated a note stating that we had for 20 years been sending foundation by mail, and that no question had ever arisen as to whether it was legitimate mail matter. We sent a duplicate packet to the department, asking them to examine carefully the same, explaining that it was simply pure beeswax embossed with the impression of the base of the honey-cell. On the 28th of March we received the following, which settles the question, at least for the time being:

Mr. L. S. Smith, P. M., Medina, O.:—You can continue to accept and forward these packages. If we have further trouble with them it may be necessary to exclude them from the mails, but this office does not feel justified in doing so as yet. Section 322, Postal Laws and Regulations, 1893, prescribes that salves and ointments must be put up same as liquids, while hard candy, yeast cakes, and soap can be forwarded when simply wrapped in paper and enclosed in pasteboard or wooden boxes. Beeswax, while having some of the characteristics of both of

these classes, really belongs to neither, and I think we can give it the benefit of the doubt until it is demonstrated that further restrictions are necessary.

ALEX. GRANT,

Acting General Superintendent.

Washington, D. C., March 28.

It seems to me that comb foundation would pretty nearly come under the category of soap. It would not soil articles in the mail-pouch any more than that article, and its melting-point would be about the same. As it is, we do not see how the General Superintendent could have decided other than to accept.

As the temperature next to the steam-pipe must have been about 180 degrees, it seems to us unreasonable to throw mail-sacks against it, and yet demand that articles in the sacks injured by such treatment should be excluded. When absent-minded Isaac Newton found his fireplace so hot as to singe his clothing and chair, he ordered his servant to come and remove it; but his servant, when he came, said it was easier to wheel Sir Isaac a little further off. "Good!" said Mr. Newton. "I never thought of that." Perhaps Route Agent Cotterman had not thought of the foundation question in that light before.

LONG HIVES HORIZONTALLY, VS. TALL OR TWO-STORY HIVES.

In my Notes of Travel I omitted to mention friend Poppleton's apiary at Potsdam. He still uses what was called, years ago, the "Long Idea" hive. Of course, you can use whatever frame you choose; and where there are no upper stories at all, a frame a little narrower and a little deeper than the Langstroth may be advisable. Friend P., like some of the rest of us, is not very strong. He says that, for years, he has not been able to do heavy work of any kind, and it would be out of the question for him to think of lifting off an upper story; therefore he makes his hives as long as the needs of the colony demand it, and has the combs all side by side. In opening a hive, nothing is necessary but to remove a very light thin cover. As a proof that his plan is not a very bad one, he has succeeded in harvesting some of the largest crops of honey made in Florida or anywhere else, and I believe the work has almost all been done by himself and wife. Of course, they have to work pretty hard when a big honey-flow comes suddenly; but with the honey-flow come inspiration and energy; and, so far, with the inspiration and energy, strength has been vouchsafed, so that no honey has been wasted. May be you have seen bee-keepers before who were unable to do hard work; but when the honey came in at the rate of several barrels a day, some way they managed to get it out. Now, friend Poppleton has quite a few disciples scattered throughout Florida, and they are sufficiently successful to show that his plan is certainly not a very bad one. May it not be that such an arrangement succeeds better in the warm climate of Florida than it would away up north, where it is so much more important to economize the animal heat of the brood-nest?

A. I. R.

ROBBING SICK PEOPLE.

STATEMENT OF THE UNITED STATES CHEMIST
IN REGARD TO THE CLAIMS OF
ELECTROPOISE.

Notwithstanding the plain and clear *expose* that has been given for months past in these pages, there are quite a few who continue to insist that the Electropoise people, and others of the same stripe, have made a scientific discovery. They admit that physicians do not accept it, but give, as a reason, that they are jealous, because "it will spoil their business," etc. Now, I felt almost ashamed to refer any thing so ridiculously and plainly a sham to such an authority as the United States Chemist; but I finally decided to do so; but in order to have the matter perfectly fair and clear, I give you my letter to Prof. Wiley first:

Prof. H. W. Wiley.—Dear Sir:—We come to you this time with something that may not be altogether in your line; but even if this is true, you could do us and the people at large just now a great service by even a couple of lines with your signature attached. Very likely you are acquainted with the humbug mentioned and described in the little pamphlet inclosed. If you are not, please turn to page 5 and read the paragraph around which I have penciled a line. Now, if you can give us permission to say that you pronounce this neither sense nor science, it will be all we ask. Should you care to say more, however, it will be more acceptable to us than you can imagine.

The inclosed galley-proof of an article that appeared recently in our journal will give you some idea of the periodicals that have been helping in the *expose*.

Your in the cause of true science, and especially medical science, A. I. Root.
Medina, O., March 27.

The pamphlet mentioned above was, of course, the Electropoise company's circular.

Well, here is his answer in plain black and white:

U. S. DEPARTMENT OF AGRICULTURE,
DIVISION OF CHEMISTRY,
WASHINGTON, D. C.

Mr. A. I. Root, Medina, Ohio:

DEAR SIR—I was much interested in reading your letter of the 27th ultimo, and also in looking over the enclosures which you sent. You ask my opinion of the marked part of page 5 of the circular which you enclose. From a scientific point of view it is rank charlatanism. I should want to go no further than such a sentence to form an opinion of the merits of the invention. I do not think, however, that I could properly give an opinion on the invention itself, as I do not claim to be an expert on electrical matters. I fully agree with you, however, that it is a humbug, pure and simple.

I am, respectfully, H. W. WILEY,
April 1, 1895. Chemist.

You will see that I expressly asked his opinion in shape so that I might make it public. I hope the above may settle the matter in regard to the scientific part of their invention. In regard to the electrical part of the discovery, all electricians have pronounced it a fraud so far as that goes; and, in fact, the Electropoise people themselves now admit that it is *not* electricity, though they did not at first.

To meet the charge that I have not made an actual test myself, let me say that I have now in my possession one of these instruments; and, after testing it thoroughly, I can say conscientiously that it amounts to nothing more than would a brass button dropped into a bowl of water, a piece of wire being attached to the button, and the other end connected with the ankle of the patient. It is true, the metal case contains sulphur, carbon, etc.; but as the case is perfectly tight, and none of the water in the bowl touches the chemicals, the said chemicals have absolutely nothing to do with the instrument. There is nothing at all about

the arrangement to make it worthy of the name of apparatus; and if it does perform cures, it is, as I have said before, exactly in line with the idea that a horseshoe nailed over a door wards off disease.

Pardon me for saying once more that this revelation of fraud that has been practiced upon intelligent people forces us to the conclusion that Tammany Ring, of New York, was not the only place that needed ventilating and holding up to the public gaze. The saddest part of the whole matter is, that it is a great part of the religious papers of our land that need the *expose*. It pains one to the bottom of his heart to see the excuses the managers have made, for continuing to accept such an advertisement. When summed up it amounts to but little less than that there is "big money" in it, and that they *need* money, and *must* have it.

If there are among our readers those who would like to help in ferreting out and exposing this fraud, I would ask them to examine the advertising department of their family papers; and whenever any thing of this sort is found, write at once to the publisher, with a protest. Mail them this number of GLEANINGS, or clip out this article, and we will send you as many copies of GLEANINGS as you can use for the purpose. We will have some extra slips preserved containing this item. Any one can have as many of these slips as he can make use of. They will be a little handier to put in a letter instead of taking the trouble to mail the journal. A. I. Root.

What therefore God hath joined together, let not man put asunder.—MARK 10:9.

There was once a schoolboy whom we will call John; and there was also in the same neighborhood a schoolgirl whom we will call Mary. Mary was a professor of religion: John may have been, but I do not exactly remember now. At any rate, they were very good people, and, I believe, they stood well in the community round about them. By accident, perhaps it was, these two became somewhat intimate in their schooldays. John, however, decided, before the intimacy had gone so far as to attract attention, that she was not exactly the woman he would choose for a wife. This may not have been through any fault of the young lady, but simply because he judged their dispositions were not exactly congenial. Some time passed; and as he gave her no more attention than he did the other girls of the school, a third party—a young man whom we will call Henry—began to be somewhat intimate with Mary. Of course, this was nothing to John, until finally Henry made some disrespectful remarks about the young lady, in John's hearing. Perhaps Henry did it on purpose to see whether John still felt any particular interest in her. John, of course, felt pained. He studied the matter over, and decided that some one ought to tell Mary what Henry had been saying, for she would most assuredly cut his acquaintance if she knew it. For reasons that may be guessed, John thought he was hardly the one to give her a warning; but as things went on, and they seemed to be getting still more intimate, Henry at the same time continuing to show a low and depraved tendency, John finally decided it his duty as a friend to Mary to suggest to her she had better cut Henry's acquaintance. Mary,

of course, thanked him for his friendly interest, and gradually excused herself for having nothing more to do with Henry. So far all went well. But this incident seemed to have opened the way, as it were, for further acquaintance and friendship between John and Mary. His better judgment told him again he had better not go on; but as Mary evidently preferred he should, it was a rather hard matter for a boy yet in his teens to break away. My friend, have you not, at some time in your life, had more or less of a similar experience? Duty points the way, but inclination does not run exactly the same way duty points; and it is no easy thing, I tell you, to always follow duty instead of inclination, especially when an interesting young woman stands in one direction and duty in another. However, John finally declared in his own mind that things had gone far enough, and turned to his studies with an earnest and manly determination to follow duty, no matter what influences were brought to bear in any other direction.

By this time, however, both John and Mary were getting past boyhood and girlhood; and when he held aloof from her she remonstrated, and finally told him that, had it not been for his interference, she might have married Henry, and all would have been well; but now it was too late. If he did not want her himself when he cautioned her about being intimate with Henry, what *did* he want? I do not know for sure, but I suspect a woman's tears came in somewhere along here. Dear friends, it occurs to me just now that I am (perhaps unconsciously) reflecting a little severely on Mary. May be some of my fair readers will say, "That is just about the way it generally goes. The *man* is all right, and the woman is *entirely* to blame." You remember how Adam, away back in olden time, undertook to make out that he would not have got into any trouble if the woman—yes, the very woman whom God had given him—had not led the way. Well, I did not mean to blame poor Mary. Very likely she was more or less at fault; but the truth is, the story came to me from John's standpoint, and not from Mary's. I still think, however, that John *meant* to do right, for they were married soon after, and every thing should have been pleasant and lovely—yes, I am sure every thing *might* have been pleasant and lovely had *Christ Jesus* and not Satan been taken into that household. I feel sure that neither one of the two *meant* to take in Satan, and I know they will both claim that Satan was not *invited* by either one; but yet he got a foothold almost at the outset. My friends, I am a great believer in letting every young couple start out in married life by themselves—that is, if it can be so managed. For a time at least they do not need a third party to manage or suggest; and if there is ever a time in the life of any person when *Satan* is not needed, it is when man and wife first begin to *know* each other. "What therefore God hath joined together, let not man put asunder." I told you Mary was a professing Christian. I am afraid, however, her Christianity was not of a real practical kind. If I could talk with her about it she might insist that it was. I think John, at this stage, made no profession whatever. Very likely he was skeptical. Still, I believe he aimed to do right—at least, as nearly right as anybody is likely to do without Christ Jesus to guide and direct. You may guess, from what I have told you, that their start-out in life was not just the best kind of a start-out, and it was not long before little disagreements arose. John was cashier in a bank, earning a fair salary, and gave promise of being a good careful business man. He had saved a little money. Of course, his

wife knew just how much, and where it was. That is right. She *ought* to have known. Some of you may object to this, and there may be circumstances that would justify the husband in keeping his business from his wife; but as a rule they two should be *one*, in business and every thing else. But Mary had seen a piece of furniture that could be bought for just about the sum of money laid aside. John protested that it would be wisdom to keep a little laid up for a rainy day, or for sickness. She suggested he could earn more, and there was no peace in that little household of two until the piece of furniture was bought, to be put into a rented house. Even the coveted object, however, did not bring permanent peace, and dissension and discord soon began again to be the rule. The advent of a bright little boy did not seem to make much difference, or the difference did not last very long, and things passed on until there were two boys and a girl to be part and parcel of that home. John was getting farther and farther away from religious influence; and I am afraid the wife was only professor and *not* possessor.

Dear married friends, do you know what a terrible thing it is for discord to get possession of a household? I wonder if *you* have ever resolved, over and over again, that you would, on your part, stop. I wonder if you have felt sad to see this thing steadily gaining a hold, and growing, almost in *spite* of any thing you can do. I remember once, years ago, of visiting a home where Satan seemed to have become so thoroughly entrenched in his work that it was really fearful to contemplate. I changed the subject again and again; but every new topic seemed to raise the same trouble as the others. I remember I praised the meat that was served for our breakfast, and innocently asked what it cost in that region. Somebody said it was 14 cents. The mother replied that it was no such thing—they got the best kind of steak for 12. The man of the house retorted that he ought to know, for he bought it and *paid* for it. And so they went on until I was really afraid they might come to blows, notwithstanding my presence. Then I said somebody told me there were a good many rattlesnakes in that vicinity. But they disputed, and almost called each other names, because they did not agree any better about the "snakes."

My good friend, were you ever in a hurry in the morning, when breakfast happened to be late? Did you ever, almost before you thought, suggest that things were *always* late in your especial household? If the good wife had been trained to the business—but I sincerely hope she had not—she might retort that you *knew* you did not have to wait for your breakfast *once a month*. You see, husband and wife get so well acquainted with each other that it is their *privilege* to talk plain; and some people pride themselves on their habit of plain speaking. God forbid. You have no more business to give pain to your wife by your plain speaking than you have to wound or hurt the feelings of some good wife whose *guest* you are. By the way, shall I tell you that a great many of my sins come right along here with that restless and impatient disposition of mine? When business is pushing—and it is almost always pushing when I am around—I am up early in the morning; and if breakfast is delayed, it is the most natural thing in the world for me to become impatient, and to scold. We expect our men, as a rule, to get to their work at about 7 o'clock; and a great many times, if I am not on hand when they start out, something goes wrong. The team may go in the wrong direction, or the team and two or three

men may all be standing still and waiting for a tool if I am not on hand to find the tool or take a new one out of the store rather than waste more time than the old tool is worth. Well, if I should start everybody off at work *before* breakfast, Mrs. Root would be annoyed by having the breakfast late, and having her work thrown out of joint. Another thing, our morning prayers very often come right in when the men and team are waiting, or something else of a similar kind. The temptation is great to skip worship for just this time. Shall we skip it? God forbid. There may be important duties to be attended to; there may be others waiting; it may be a question of duties; but my verdict, after long years of experience, is that we had better delay almost any thing else, or, I might almost say, *every* thing else, rather than think of skipping the daily Bible-reading and prayers. A good friend of mine has said, "Stick to your family worship, and it will drive out all discord;" or, in other words, "if discord does not drive out family worship, then family worship will *surely* drive out discord." I *know* how distasteful it is to think of taking the Bible in hand just after you have been scolding or contradicting; but I have sometimes thought that we might consistently sum it up in the words of the old veteran commander Joshua, "Choose ye this day whom ye will serve." I do not know for sure that the husband is *always* the aggressor. I am afraid, however, he usually is. In a fit of impatience he makes a statement, and overstates it. When you are vexed, Satan always stands at your elbow, and urges you to put it *strong*. If you listen to him you will go so far that your wife takes it up and says, "Now, that is not true, and you *know* it is not." The latter, of course, is an additional sting to the lash; and Satan prompts you to reply, even though you *know* better when you say it, "It is true." By this time your faces are both flushed. Children are *very* apt learners in such matters, and the disease is *terribly* catching. It pains my heart as I go over it now; and yet I have, during my travels, heard almost or quite as bad as the above, even while I, a stranger, was present. Dear friends, do not be alarmed. It was not in a bee-keeper's home, and it was years ago. Perhaps I have taken an extreme case. I sincerely hope it is extreme. But now and then I get glimpses of the outcome of these things. It grows and grows; and the very best disposition in the world is hardly proof against it if one remains long where it is going on. Were I so disposed, and if Satan would lend his help—and, by the way, he is always exceedingly *ready* to help—I verily believe that I could, in process of time, make the sweetest-tempered man or *woman* in the world bitter and hard and ugly. I have been told sometimes that I have a *rare* talent for provoking people, when I feel that way. God helping me, I never mean to use that talent any more; and if I have such a talent, Christ Jesus has, I believe, given me another talent or gift. It certainly must have come from him, for it never belonged to A. I. Root himself—a talent for helping people to be gentle and kind—to turn away wrath with a soft answer. To turn the figure round, Christ helping me I have sometimes thought that, by taking plenty of time and great pains, and much prayer for help, I might succeed in taking one of the most bitter, hard, and ugly persons, and making him gentle and kind. It is hard work, though. A grown-up person who has fallen into a way of being hateful can be made to give it up and become sweet-tempered, only by a *tremendous* deal of hard work. It must be "line upon line, precept upon precept." It must be a continual rendering of *good* for *evil*, and replying to hard

and cutting speeches with soft and gentle answers right straight along for months, and perhaps *years*. The disagreeable person must be loved with no *common* love. That 13th chapter of I. Corinthians tells how it is done. You must suffer *long*, and be kind. You must not get provoked, no matter what happens. Neither must you even *think* evil—"beareth all things, believeth all things, endureth all things." This is the way the teacher must go to work to redeem the pupil. I know it can be done, for I have seen it done. A gentle, loving, pious wife or mother has again and again transformed a bad and wicked man, with Jesus' help. When I heard the story of John and Mary I felt to wondering how it would have turned out had Mary been *my* wife—I mean, suppose I should have been suddenly converted when well along in life, and suppose my wife was not converted, but remained just the same. The man is the stronger of the two; and if he succeeds when he takes the lead in educating his wife to discord, he can usually, by *taking the lead*, and asking for grace, lead her back to gentleness and grace and truth; and when it is done—when you have succeeded in winning your *wife*, oh what a *glorious* victory! If there is joy in heaven among the angels over a reclaimed *sinner*, what joy must there be over the mother of a home, who has been reclaimed and brought from darkness into light!

If you should be away from home, the invited guest of some well-bred people, you would never think or dream of grumbling—no, not even if the breakfast were so late as to cause you to *miss your train*. Now, if there is any one on earth who demands your most gentle bearing and your kindest courtesy, it is the wife whom God gave you. Some of you may suggest that God did not give her—that it came about something the way I have described in the story of John and Mary. But, my friend, you are wrong. "What therefore God hath joined together, let not man put asunder." If you are lawfully wedded man and wife, that is enough—the command of our text holds. If there are *children* in the home who belong to you two, then a *sacred seal* has been placed by *God himself* on the union that exists between you; and whether you, during the marriage ceremony, promised to honor and cherish this partner or not, all mankind and God himself expect you to do so.

I shall have something further to tell you in regard to John and Mary in our next, Providence permitting.

FINDING WATER WITH A SWITCH.

SEVERAL good friends have written me that this thing is true and honest, and that there really is a force in nature, heretofore unrecognized by science and scientific men; and several declare they can trace underground streams as you would trace a stream or brook on the surface. Now, this is going to make the test comparatively easy, if it is true: First, have a row of stakes set, outlining the course of the underground stream; then let the operator be blindfolded, and see if he will set some stakes along the same line. When you find a person who succeeds in doing this, then I am ready to pay him a visit, and perhaps take along some one from some of our experiment stations, so as to have the matter tested by a competent official.

A. I. R.

PINEAPPLE-GROWING, ETC.

Now, then, if you please, let us go back to pineapples. I think my last Notes of Travel were when I was stopping at Mr. Poppleton's. It costs from \$50 to \$75 an acre to clear up the land, and get it ready for pineapples. It is mostly done by hand, digging out the saw-palmetto roots and other trash. These saw-palmetto roots, however, are quite valuable. The State Chemist at Lake City told me that fresh roots, burned to ashes, show 42 per cent of potash—that is, 42 per cent of the *ashes* is potash. This is remarkable, when we consider that the best hard-wood ashes seldom contain more than 8 or 10 per cent, and often not half of that; and potash is in constant requisition in Florida in considerable quantities. After the land is all ready for the plants, it needs from \$25 to \$50 worth of fertilizers every year. The crop of pineapples, however, brings from \$100 to \$400.* The fertilizers used are cotton-seed meal principally; a good deal of sulphate of potash, some fish guano, and large quantities of fertilizers from the North, are used right along. Mapes', Bradley's, and Bowker's are all largely used. Pineapples are cultivated about once a month, with a scuffle-hoe. The work is all done by hand. Mr. Dyer, a neighbor of Mr. Poppleton's, had a few that withstood the December freeze, and we enjoyed beautiful fruit all the time we were in that neighborhood. There are, perhaps, a dozen different varieties of pineapples in cultivation. Some of the new varieties sell as high as 40 or 50 cents per plant. We rather thought the "sugarloaf" the most delicious. There is no seed to the pineapple—at least, I never heard of one.† New plantations are made from little plants, and the little plants are obtained in four different ways: First, the crown that comes out of the top of the pineapple; second, slips that grow around the bottom of the fruit; third, suckers; fourth, ratoon. The ratoon is a little plant that starts up out of ground somewhere near the mature plant.

In many places they protect from the frost and sun by means of strips of board. This

forms a sort of roof above the plants, just high enough so one can walk under it. It is supported by posts. The strips of board are three inches wide, and the space between the strips is three inches. The cost of covering a whole acre is about \$800. This protection keeps off any ordinary frost; but during the severe freezes of February, the protection did not seem to amount to very much, unless it was pretty well south. At Fort Myers, for instance, the plants seemed to be almost, if not quite, uninjured underneath the covering.

Friend Poppleton kindly took us in his sailboat, and we visited pineapple-growers and gardeners for quite a distance round. Florida is just commencing to do considerable in the way of irrigation. The nicest apparatus we found on the East Coast was at Dr. Howland's, who has a gas-engine, such as I have described, for pumping water. We found it down in the woods, at work all alone by itself, pumping the water out of a spring. The doctor was in his garden with his men, perhaps a quarter of a mile away, at work with his crops. He has iron pipes laid on top of the ground, 20 feet apart. At intervals of 20 feet along these pipes a $\frac{3}{4}$ -inch standard goes up perhaps four feet high, having a revolving sprinkler on top. This gives the effect of a gentle rain all over the ground where the pipes are laid. The capacity of the engine is hardly sufficient to pump water enough to sprinkle the whole acre at once. Perhaps a quarter of an acre is sprinkled at a time; but by running it about four hours, the ground seems to be sufficiently wetted. In Florida they are hindered a great deal by different kinds of insect-enemies; and certain kinds of garden vegetables, in some localities, can not be grown at all on account of these. Well, the doctor informed us that the sprinkler proved to be a perfect remedy for these pests. There are not many kinds of insects that can do much damage while it is raining; and with the light, sandy soil they have, there is not very much danger of injuring anything by too much wet; therefore the doctor had some of the most beautiful summer squashes, onions, beans, and almost every other vegetable, just smiling under the influence of water and sunshine all at the same time.

During our many pleasant boat-rides around the home of friend Poppleton, we met again and again the queer phenomenon of a tree having limbs at both ends. One set of limbs goes up into the air, and the other set goes down into the water. As a consequence, in the course of time one single tree may cover an acre or a whole island with its growth so dense that nothing larger than a cat or dog would be able to get through. This queer tree is called the red mangrove, or aerial plant. According to Webster it "spreads by emitting aerial roots, which fasten in the saline mire and eventually become new stems. The seeds also send down a strong root while yet attached to the parent plant. The fruit is sweet and eatable. The bark is astringent, and is used for tanning." It does not bear honey, or, at least, not enough to be of any actual use like its near relative the black mangrove. The seed is a queer-looking thing, about the size and shape of a cigar. When it drops off into the water, one end sinks and the other end floats on top. When it comes up near the shore, so the lower end touches the bottom, then roots put out, and the queer-shaped tree is the result. Whenever one sees these queer-looking trees skirting the edge of the shore or an island, he thinks of the banyan-tree that we used to look at in our geographies, away back in the old schoolhouse on the crossroads.

While visiting the pineapple groves we saw

* Like most other fruits and vegetables, there is a chance to do big things with pineapples under favorable circumstances and with the best of care and fertilizers. For instance, Mr. Poppleton sent six pineapples to Jacksonville, and they sold for \$1.25 each, and he actually received from the commission merchant \$1.00 apiece for them. I think they weighed 15 or 16 lbs. each. A pineapple has been produced in that neighborhood, having the enormous weight of *twenty-two* pounds. I mention this only to show the possibilities in that line.

† After the above was in type, friend Poppleton kindly sets me right, and gives us the following information:

Friend Root:—Pineapples do have seeds, either a mature or immature one in each eye. You may remember I told you that the apple had a small purple blossom at the point of each eye. I don't think any were quite far enough along when you were here to be in bloom; but you might have seen them later on when you were at Fort Myers. Mr. Johns told us the sheds we visited near here were so much of a protection that the February freeze did him no damage. Ordinary seasons we have ripe pineapples every month in the year. The main crop comes in June and July; but a plantation of, say, 10 acres would ship a few crates to market every month in the year, except, possibly, April and May, and would have enough more ripening along at all times to fully supply a family.

Potsdam, Fla., April 4.

O. O. POPPLETON.

a queer animal washed upon the shore, about the size of a cow, and with a head looking considerably like that of a cow. This is called the sea-cow, or "manatee." Friend P. tells me these are quite common in these waters, notwithstanding the fact that many of them have been exhibited in shows as being "the only living specimens," etc. These animals are 15 feet or more in length, and are found both in fresh and salt water.

About the 7th of February, we bade adieu to the kind friends at Mr. Poppleton's, and moved on further north to Gifford Station. Constance had got rather used up by mosquitoes at Lake Worth, and moving about so constantly every day, so she went back to Jacksonville for "repairs." Even if Gifford was in the wilderness, I found a very good road for my wheel, and in due time reached the Gifford mansion. This is only about a quarter of a mile from a town called Vero. But the conductor would not let me off at Vero, so I had a wheel ride as a consequence. As I came at a time when they were not expecting me, I found no one at home but a miss of ten years old. She and I soon became excellent friends. She told me how they managed the postoffice, and said she could do it all herself; and I was greatly surprised to hear her answer questions that I put to her in regard to general postoffice business. Her name is Ruby. She not only told me about the postoffice, but about the neighbors and other things. They are so far away from everybody that they have no schools for her to attend; and, in fact, there is not any little girl for a playmate within miles in any direction. The State of Florida, however, is not forgetful of her children. There is a provision by law, so that each pupil receives, if I am correct, \$10 for a term of 16 weeks. The county superintendent decides, at his examinations, whether the money has been well expended. Accordingly, I found my young friend Ruby remarkably bright and ready. I suppose one reason why we became fast friends in so short a time was that she rather hungered for companionship of any kind. If she could not have a little girl to talk to, a man 55 years old, like myself, would do a great deal better than nothing.

After a while I took my wheel and went out to meet her brother, who was at work with the horses and farming-tools, a couple of miles away. You see, friend Gifford has horses and wagons, etc., after all. And, by the way, he has some land around him that *warrants* having Northern tools. It is not all sand, let me tell you. After I found Charles (Ruby's brother), I went out to meet friend Gifford himself. His garden was of wonderful interest to me, especially the new, strange fruits. There were mangoes, guavas, mulberries, sugar-apples, tamarinds, sour-sops, cherries, grape-fruit, etc. The last-named tree was left with part of its crop hanging to its limbs for my special benefit. The tree was scarcely as high as my head, only three years old, and yet it had borne three bushels of fruit. One bushel remained on the tree, left for me. The grape-fruit grow so close as to touch each other, and I believe this has suggested the queer name—grape-fruit. When one is tired and thirsty during hot weather, it is wonderfully delicious.

When I arrived the mulberry-trees were bending with loads of berries almost big enough to begin to turn red. During the night, however, both berries and foliage were literally coated by the frost.

Friend Gifford is an enthusiast on mangoes. It is a tropical tree of most rapid growth, and the fruit is greatly sought for after one has learned to eat it. Friend G. is satisfied that it has wonderful curative properties, especially

where one is troubled with disordered stomach or bowels. Some people, who have not learned to eat it, say it tastes like cotton batting soaked in coal oil; but, notwithstanding this, others are so extremely fond of it that the fruit on a single tree at St. Lucie, one season, brought the sum of \$150; and Mrs. Prange (who is kindly taking down these notes for me) adds that the family found this one tree their main support. In fact, it is about all they have to get a living from. Now, when I was writing, a few months ago about supporting a family on a *quarter of an acre*, some of you were inclined to make fun of the idea; but here is a family depending upon a single fruit-tree, without saying anything about as much land as a quarter of an acre. When I expressed my incredulity in regard to this statement, friend G. said the man's name is Alec Bell, and that I could easily get the full facts if need be. He added, however, that one reason why they received so much money from the crop was that it seemed to be an extremely fine variety, and many sold for an extra price because the parties buying wanted the seeds to plant. Friend G. added further, that there were mango-trees standing in his garden that he would not have taken \$100 for, before the December freeze. I suggested that, for \$100, he could have covered the whole tree, trunk and branches, with a heap of dirt; and this, indeed, might have been done, or something like it, in many cases; but the first came "like a thief in the night," and nobody thought it was going to hold on so long without letting up.

Another of friend Gifford's hobbies is Japan persimmons. This is a new fruit that has not been very much grown in Florida; but fine specimens, I am told, have been sold for a nickel apiece. The fruit of a good variety is as large as a good-sized peach; in fact, they have been raised $4\frac{1}{2}$ inches in diameter. And this fruit is clean pulp clear through—there is not a stone or seed of any kind. The tree is a wonderful grower, like the mangrove, and I think it has not been very much harmed by the freeze.

Another of the Florida fruits is the Avocado pear; but almost everybody calls it the "alligator" pear, because it comes handier to say alligator than "Avocado;" and after you have it said, it is not a pear at all, even then; but it is a beautiful fruit. Did I tell you that Florida is the greatest place I ever saw in the world for fertilizers of every sort? Why, the outbuildings of even the humblest home to the biggest hotel are almost invariably provided with galvanized iron pails, or some equivalent (Terry's plan, you remember), to receive and preserve the night-soil. When anybody wants to plant a tree he digs quite a little cavity, pours in a pailful of this night-soil, mixes it with the sand until it is thoroughly incorporated, and not at all offensive, then plants the tree, and it has a good send-off. No matter what a man works at, he has some trees or fruits of some kind growing in his dooryard, and therefore he is interested in saving everything in the shape of fertilizer. Well, near friend Gifford's home there are great droves of wild cattle; and up near the river there is a clean spot of ground that, for some reason or other, is almost free from vegetation. Here the cows come to lie down nights. At intervals friend Gifford goes out with his wagon and scoop-shovels, and gathers up the "cow-chips" as they call them in Florida. His beautiful fruit-orchard is fertilized almost entirely by this manure.

On one of our visits we called on a Mr. Weis. This man, although he lives a sort of hermit life, all by himself, away out in the swampy woods, where not even a road of any kind runs anywhere near him—this poor lone bachelor friend has one of the prettiest gardens I ever

saw. We found bananas, date palms, potatoes, cabbage, string beans, and even some beautiful flowers, and nobody but himself to enjoy them. You might have known I would have made a protest against such a waste. Why, there are *thousands* of industrious, intelligent German women who would *delight* in finding such a home, and they would give this poor, lonely man a glimpse of happiness and companionship such as he has never *dreamed* of; and then there would probably be some reason, in course of time, for building a neat little *schoolhouse* away down in those Florida wilds.

Several times I wondered why it was that everybody in Florida was planting beans; and it was just one kind of bean, too—the Refugee, or Thousand-to-one. They say the golden wax beans do not do well in Florida; but they produce this one kind of string bean. I did not see any beans in Florida, however, with the rank, luxuriant growth we have here on our clay soil; but when I suggested as much to friend Gifford, he replied that they sometimes sold a single crop for \$400 per acre, even if they did not get such tremendous crops as we do. His daughter, Mrs. Sprange, here puts in, by way of parenthesis, that sometimes the crop brings nearer 4 cents per acre.

Ruby's mother died of consumption less than a year ago. They brought her to Florida when it was too late, although her life was prolonged several years, so the friends believed, in consequence of getting to Florida when she did. The cook of the family, while I was there, was a boy who had formerly served in that capacity on board of a steamboat. In consequence of dull times he was out of employment, and friend Gifford took him in, and I found him making himself exceedingly handy, indoors and out. In one of our trips through the woods, we came across a deserted plantation, where orange-trees were planted twenty years ago. Nobody has tried to do anything with it for years past, and the place has all grown up to forest; but the orange-trees, mostly the sour variety, grow right out in the woods, and bear considerable crops. I found some of them that had escaped the frosts, and I thought them quite delicious.

Almost all through Florida, bee-keepers complain of the depredations of bears. Once upon a time a bear visited an apiary where there were cases of sections all ready to come off. The bear took off the top of the hive, then took two cases of sections, one under each "arm," and started off for the forest. I presume he was a little bashful about sitting down and eating his honey there so near the bee-keeper's home. The owner of the hives, however, heard the racket, and put out after him. The consequence was, Bruin dropped his cases of honey in the bushes, and put off without them. I asked the owner if he actually *saw* the bear going off with a case of sections under each arm. He admitted that he did not see the operation, but replied, "But, Mr. Root, how else *could* he have carried them? Please tell, will you? I chased the bear away, picked up my two cases of sections which he dropped on top of the bushes, so as not to break or injure them; and, in fact, they were in such good order that I shipped them both to New York, and sold them with the rest. Now, how did the bear carry those two cases out into the woods unless he had one under each arm and walked on his hind feet? Please tell."

Now, friends, I am sorry to say that I can not at this very minute tell who told me this bear-story. It sounds very much as if it were A. F. Brown; but if he absolutely declares that he did not tell it, then it must have been somebody else.

I suggested to friend Gifford that he should

keep store in connection with his postoffice, and that Ruby would make a tip-top clerk. But he said he had had "store" enough in the North—that he does not want to be bothered any more. There is not a store or grocery of any sort within six miles of him. I happen to know, however, that he does quite a retail business as it is, for Ruby says they sell oranges for a cent apiece, and honey for 5 cts. a pound, at retail.

You remember what I said about the Weather Bureau and the oranges? Well, during the freeze of Feb. 7 I had an opportunity of seeing something of the difficulty of transmitting cold-wave messages in the interior of Florida. On the 6th of February, about 10 o'clock in the morning, Jacksonville was notified that a cold wave would reach there during the night. This message was promptly telegraphed to Titusville, where they ran up the cold-wave flag. The displayman also mailed cards of warning to all the postoffices in the county. One of these cold-wave cards passed Vero postoffice on the train at 7 o'clock in the evening. There is so little mail in the evening, however, that they have decided to let it all go down to West Palm Beach, and come up the following morning at 10 o'clock; and, accordingly, at that time next day, we were notified of a cold wave coming. We got the notice several hours after the mischief was done. Now, this happened right on one of the main lines of railway too; how would it be several miles away from either railway or telegraph lines?

THE NEW CATALOGS.

Look out for the catalog that praises *every* thing unstintedly, and especially where the good qualities are mentioned of every fruit and vegetable, and none of the objectionable qualities. We have catalog men now who report almost as faithfully and disinterestedly as do our experiment stations, and these men should be encouraged and patronized. Take the Timbrell strawberry for an illustration. How many of the catalogs tell you that, while it is one of the grandest new berries, it has one very objectionable feature—a mottled white tip, even when the berries are perfectly ripe?

VARIATION IN PRICES OF POTATOES, ONION-SEEDS, ETC.

If you will look over the seed-catalogs you will see what a wide margin of prices is given on the same article. For instance, one seed-catalog will put seed-potatoes at \$2.25 per bushel, while another one quotes the same variety at \$2.25 a barrel. Again, some of our leading seedsmen in the great cities are still asking \$2.50 a peck for onion-seeds, potato onions, multipliers, etc., while other friends who live out in the country are offering the same thing, and would be glad to get \$2.50 for a whole bushel. Perhaps it is no particular business of ours; but I would advise that, before you send off your hard earnings, you look over the agricultural papers and see the bargains offered in their advertising columns, and also look carefully over the catalogs sent out by practical farmers.

WHITE VICTORIA ONIONS.

I believe we were among the first to introduce and recommend these beautiful fine large onions; but of late there has been more or less

complaint that the seed produced onions of different kinds, not true, etc. In Burpee's 1895 catalog we find the following by way of explanation:

Since first introducing these onions, we have each year heretofore imported seed direct from the original growers in Southern Italy (whose gardens we have several times visited); but we regret to announce that the seed sent in the autumn of 1893 (for sale last year) *was not true to name*. Therefore we have been forced to discontinue the sale of imported seed, and now offer *exclusively AMERICAN-GROWN SEED*. Unfortunately, the Italians do not seem to realize the importance of *purity in seeds*, but we did think that we could rely upon the original growers maintaining, by careful selection, the true type of these Victoria onions. Fortunately, however, much of the seed sold last year had been grown for us at home, so that all our customers who ordered Victoria onions did not receive the inferior Italian-grown seed; but those who did, if they will kindly notify us, are now entitled to select fresh American-grown seed, to the same value, without cost.

W. ATLEE BURPEE & CO.

We are glad to see the above from friend Burpee. It has the right ring; and we make the same offer to all who bought seed of us of the White Victoria. If it did not prove to be what it ought to be, tell us how much seed you had and when you got it, and we will send you good seed, or, at least, seed bought directly of Burpee, in place of it.

PARIS GREEN TREATMENT FOR CODLING MOTH.

The United States Department of Agriculture sends out the following:

Secretary Morton, in an interview to-day, said:

"The apple-trade of the United States with foreign countries has always been profitable. The demand for apples grown in the United States has always been in excess of the supply. The United Kingdom of Great Britain alone, during the nine months ending September, 1894, paid the orchards of the United States \$2,500,000. The greatest enemy to our export apple is the 'codling moth.' But the entire crop can be made wormless if the orchards of the United States will use the following recipe:

"Use Paris green at the rate of 1 pound to 150 gallons of water. Weigh out sufficient poison for the capacity of the tank used, and make it into a thin paint with a small quantity of water, and add powdered or quicklime equal to the weight of poison used, mixing thoroughly. The lime takes up the free arsenic, and removes the danger of scalding. Strain the mixture into the spray-tank, taking care to pulverize and wash all the poison through the strainer. During the operation of spraying, see that the liquid is agitated with sufficient frequency to prevent the settling of the poison.

"The prime essential in spraying is to break up the liquid into a fine mist, so as to coat every leaf and part of the plant as lightly as is consistent with thoroughness. This should not require more than from 3 to 7 gallons for a comparatively large fruit-tree.

"Let the first spraying follow within a week after the falling of the blossoms of either apple or pear, and follow this with a second treatment just before the fruit turns down on the stem, or when it is from $\frac{1}{4}$ to $\frac{1}{2}$ inch in diameter. The first spraying reaches the eggs laid by the moth in the flower end of the fruit, shortly after the falling of the blossoms; and the second, the later eggs laid by belated moths. Do not spray trees when in bloom; and if a washing rain immediately follows treatment, repeat the application.

"Knapsack sprayers suitable for applying the insecticide can be obtained at reasonable prices at all agricultural-implement stores."

Washington, D. C., March 23.

THE ONION-MIDGE.

This insect is so small that it can hardly be seen by the naked eye. I had just as thrifty onions last year as anybody could wish to see; then all at once they commenced to die from the top down, before they had begun to bottom. I went to work and sprayed them with Paris green, but that did no good; then I spray-

ed with London purple, and that did no good. Next I took slacked lime and put it into a coarse sack and dusted the onions in the morning when the dew was on. I made them clear white, but that did no good. Then I got some soot from the chimney and dusted them early in the morning, and made them clear black; but they worked right on, and killed all my sets and the big onions too. Are there any of the GLEANINGS readers who know any thing about the insects? I should be glad to find out what to do to get rid of that onion-destroyer.

HENRY PAULUS.

New Philadelphia, O., Feb. 12.

I myself have been considerably troubled for fear the onion-midge might commence again in our locality as it did last season. Some of the onion-growers think, however, it was mainly caused by the drouth—that plenty of rain would have drowned them out, or at least hindered their enormous propagation. I am glad you have tried all the things you have mentioned, and reported to us, for it will save others from going through the same experiments. On page 596 of this journal for July 15, 1894, I described the onion-midge, and said that our experiment-station folks visited the large onion-fields, and made some experiments; and they decided, I believe, that the only feasible remedies were tobacco tea or dilute carbolic acid. The latter will be the cheaper—one part of carbolic acid to 100 parts of water put on the onion-tops with a spray-pump. If our Ohio Experiment Station, or, in fact, any other, have any thing better to offer than the above, we shall be very glad indeed to hear from them. Our American Pearl onion is so early that it has so far matured a crop before the midge really got to work.

WATER CRESS—A CAUTION.

This variety is what the English and German people are so fond of. I have a large spring in which, a few years ago, some roots were set. They increased very fast from seed floating down stream, and soon filled the open ditch, and choked the side drains, and caused the sediment and mud to fill the ditch for a mile in length. This had to be cleaned out at great expense to avoid flooding the ground. A word of caution here may save you a world of trouble. It sells readily, tied in bunches about what your hand will reach around. I get 2½ cts. a bunch wholesale, and 5 cts. retail. Where it is kept at stores it is set in pans with an inch of water or more, where it will keep without wilting, for some time. It is used in hotels to garnish dishes, and is eaten similarly to celery, by dipping in salt. Some use vinegar, the same as in eating lettuce.

CHAS. MILLS.

Fairmount, N. Y., Mar. 24.

FIVE SASHES.

Several years ago I got five sashes. April first I helped prepare a bed, and had a kind hand make a frame to put over it. The sashes cost me \$6.50, the lumber \$1.00. I placed the thermometer inside on a nail, and brought out my seed-basket. I put in a row of celery four inches from the front of the frame, always in the coolest shaded place; then crosswise, several rows of tomatoes; then one and a half sashes were sowed to Grand Rapids lettuce; then cabbage, sage, and cauliflower. We had lettuce for general family use in three weeks, and used daily till garden lettuce was ready. We sold \$4.40 of cabbage and tomato plants, besides setting a large garden at home. The tomatoes were dropped seed by seed about an inch apart, of Dwarf Champion sort, and made the

finest plants I had ever grown. For earliness, robust growth, satisfactory fruit, and freedom from disease, I grow the Champion. My five sashes have since been my delight, and twice paid for themselves, besides the home pleasure and benefit.

MRS. L. J. PAGE.

Faribault, Minn.

FLORIDA UP TO DATE, ETC.

The Alec Bell mango-tree story is rather large, but you haven't told it all, even yet. It was *three* years instead of *one* that the fruit sold for \$150. I have the finest beans I ever saw; shall commence shipping this week. Potatoes, cabbage, and watermelons are looking well. Japan persimmons are loading with fruit. If half hold on, the trees will have to be supported.

Bees are doing well. I am painting all of the hives over new, and shifting all the bees into newly painted hives, taking pains to cut out all burr-combs, and to put all drone-combs in upper stories.

H. T. GIFFORD.

Vero, Fla., Apr. 8.

SWEET CORN.

We have found an excellent demand for our crop of fresh sweet corn in neighboring city markets. City people seem to find it quite difficult to get their corn fresh. After it has lain in the stores a day or more it rapidly becomes tough and stale, and its quality rapidly depreciates, until soon it is hardly good for any thing. Consequently, corn freshly gathered, brought in directly from the farm, is a welcome article. To make a good succession through the season, sow Cory first, then Minnesota, and last, Stowell's Evergreen. The last should be sown several times at intervals of ten days, to have plenty of corn until frost comes. The early corn will probably bring at retail 20 to 25 cts. per dozen. Soon it will fall to about one cent an ear; but even at this last price there is a fair margin of profit, especially when the stalks are prized as horse or cattle food, as they justly should be. The feeding value of the stalks materially reduces, even if it does not quite offset, the cost of cultivating the entire crop. A fair estimate of the proceeds from an acre of sweet corn would be from \$75 to \$100; and, considering the labor expended, the sweet-corn crop averages about as well as the majority of farm and garden crops. One good thing is, that corn is not over-particular as to soil. A tough sod, turned over in May and enriched with fine barnyard manure, answers well for this crop. Or we may use nitrate of soda, superphosphate, and wood ashes, if we have not the manure to spare.

STRAWBERRIES.

The strawberry is the most luscious of small fruits, and the spring is by all odds the best time to set out plants. At the outset, take some care to secure vigorous young plants for setting. The common opinion seems to be, that any young plants that will grow answer well enough—a great mistake. We want young plants from large vigorous older plants, that have never been allowed to produce a berry. Fruiting-beds, and beds for propagating-purposes, should be regarded as distinct affairs. It is desirable to have the plants we are to set out come from the strongest parent stock possible. Next after getting the proper plants comes the planting. To secure the largest possible specimens of berries, confine the plants to hills 18 inches apart in each direction, only one plant in a hill; but to secure the largest crops of large berries, grow strawberries in *their* beds. A closely matted strawberry-bed means small, soft, poorly flavored berries.

Plants of almost any vigorous-growing variety, if set in early spring in rows four feet apart, the plants two feet distant in the rows, will cover the ground as closely as is desirable during the season. To cause the runners to cover all spaces uniformly, it is well to arrange them by hand in any cases where they do not properly separate naturally. By placing a little fine dirt just above the roots of the runner it will be held in place, and the process of rooting facilitated. Apply wood ashes for fertilizer, and cultivate often till the vines obstruct the work.

M. SUMNER PERKINS.

Danvers, Mass., Feb. 8.

MICHEL'S EARLY STRAWBERRY.

I am sorry to see Michel's Early in the list of "poor" ones at your agricultural station. I am growing Bederwood, Bubach No. 5, Crescent, Jessie, Michel's Early, and Warfield; and Michel's Early made the best stand of plants and gave the most berries (nice perfect ones too) of any of them. For one I shall not give up the Michel's Early yet.

Eldora, Ia., Jan. 19.

J. W. BUCHANAN.

WHAT SHALL WE DO?

WE can not take very much space in such a journal as this to discuss the financial and social matters that seem to be filling our newspapers at the present time; but I hope I may be pardoned for this suggestion: A great many people seem to claim that the world owes them a living and does not pay it. I fear this is bad philosophy. The world owes no man anything until he has earned it. When he has earned it, the world *generally* pays it. If manufacturers, bankers, etc., are so greedy and dishonest, do not have any thing to do with them. My father went into the woods, and chopped logs enough to build a house, brought up a family of seven children, without any help from manufacturers or millionaires, and it seems to me that is just what our people ought to do now. God surely helps those who help themselves.

A. I. R.

DAYLIGHT AHEAD.

YOU may remember that, when Dr. Wilford Hall got to doing an immense business in selling his internal water cure at \$4.00 for each secret, there began to be imitations. Somebody offered the same thing for \$2.00, and then somebody else came down to \$1.00, and so on to 50 cts., and lastly to 25 cts. At the latter figure there was not enough money in it to cause a great scramble any longer, and so the whole thing went down, and the secret was published in the papers. It is now getting to be just so with Electropoise, and a \$5.00 machine is already advertised. Very soon they will be down to \$1.00, and perhaps 50 cts. The question is, will the 50-cent one cure diseases just as well as the \$25.00 one? I am afraid it will not—not even if they should sell the very same thing that is now selling for \$25.00, for 25 cts. There is a tremendous lesson to be learned right along here; but will the people learn it? Will those who have been paying out so much money for medicines and expensive apparatus have grace to admit they made such a blunder in thinking the thing really did possess virtue?

A. I. R.

BEE SUPPLIES.

I will give 10 per cent off for cash orders of \$5.00 and over up to May 1, '95. Send for free catalog to manufacturer.

J. J. BRADNER, MARION, IND.

In responding to this advertisement mention GLEANINGS.

FARMERS SHOULD EXPERIMENT

and not always take the word of interested parties. Very few of them have any idea how much the common soft wire will stretch. They may have been lead to believe it a mere trifle. It is an easy matter to prove that a No. 9 wire, under a strain of about 1000 lbs. will stretch from 1 to 1½ in. per foot and it never takes up its own slack. That accounts for those little end ratchets filling up so quickly. Our local agent will furnish a powerful stretcher for this experiment.

ODD-LOT SECTIONS.

Of the list of sections offered in last issue at special prices, we have sold the 1½ open top and bottom, but still have the other sizes listed.

BUSINESS CROWDING.

We are having all we can manage to keep our orders filled with reasonable promptness. Some orders for odd goods which have to be made are delayed longer than we like to have them; but we hope, by putting in extra time, to keep pace with the orders, and get goods out promptly.

There will be a good demand this spring for bees by the pound, nucleus, and colony, owing to the heavy losses in some quarters. We do not now sell bees ourselves, and there are only one or two who advertise nuclei in our columns. If you have bees to sell, advertise; but get your announcements in quick if you desire to catch the orders.

ONE PIECE SECTIONS.

As a sample of the way our one-piece sections go together without waste from breaking, we mention the fact that, during the past week, one of the girls in our employ folded on a Hubbard section-press, in less than half an hour, 500 sections taken from stock, only two of which were broken in folding. These sections, when folded, are much more rigid than any four-piece section can be unless glued. Think of the time saved in putting together, as well as the saving in first cost.

HONEY MARKET.

Our last call for extracted honey has brought us a number of favorable offers, some of which we have accepted. We are again able to supply choice extracted honey in 60-lb. cans, 2 in a case, at 8½¢; two-case lots or more, at 8¢; in 115-lb. kegs at 8¢, or direct from Wisconsin at 7¢. Barrels of 550 lbs., direct from Indiana, at 7¢. Special prices on large lots. These offers are subject to previous sale. We have calls for choice white comb honey. If any of our readers still have some unsold we should be pleased to hear from them, stating quantity, price and how put up.

WIRE FENCING AND NETTING.

The attention of those interested in fencing is directed to our advt on another page, offering special bargains in remnant rolls. This has not appeared since last June; and by comparing prices now and then you will find a marked reduction clear through the whole list. You will find at present prices some decided bargains in the list. We have in stock here 6 rolls of 3-in. mesh, No. 17 wire, 48 inches wide, which we offer at \$3.60 per roll, or the 6 rolls for \$20.00. This is a size not regularly kept in stock, and it will make a very desirable yard fence.

SECOND-HAND FOUNDATION-MILLS.

Two or three weeks ago we were sold out of second-hand mills, all but one six-inch. More have come in since, so that we now have the following list to offer:

Six-inch, No. 1467, hex., thin-surplus mill. Price \$12.00. This is the mill exhibited at the World's Fair, and was for a time used in our wax-room. It is good value for the price.

Six-inch, No. 1631, hex., thin-surplus mill. Price \$10.00; good value at the price.

Ten-inch, No. 1723, hex. Price \$12.00. This will make foundation 6 or 7 feet to the pound; was used in our wax-room, and is still an excellent mill, except for a blemish in the rolls, caused by a small hard substance passing through in the wax.

Ten-inch round, No. L L. Price \$14.00. This is a late-pattern mill, and in excellent condition; suitable for medium foundation; practically as good as new.

Ten-inch round cell, old style, No. M M. Price \$10.00. This mill has the old-style frame; was made a number of years ago. Although used very little it shows the great advance we have made in the

manufacture of these mills. It will answer nicely for heavy foundation.

Ten-inch round-cell, old style, No. N N. Price \$11.00. This answers to about the same description as No. M M, but is in a little better condition. Either of these is good value for the money.

Besides the above we have a number of new six-inch mills which are far superior to what we sent out a few years ago, but are not quite up to the present standard of excellence required by the large users. We will sell these mills at from \$12.00 to \$15.00, depending on value; will submit samples and full particulars to those interested, on application.

DOMESTIC ECONOMY.

I do not know of any thing of more importance to the inmates of the homes of our land just now than this matter of domestic economy; or, in other words, in deciding how to make what money there is go the furthest. The first real start I ever made in the world, financially, was by making the outgoes less than the incomes; and Mrs. Root and myself gave the matter as much study in those earlier years of housekeeping as we would give to one of the fine arts—perhaps even more study. We learned not only to make every thing go as far as it could be made to go, but to utilize all the waste products. In the last few years it has been my privilege to get occasional glimpses of the inside workings of many homes, and it has pained me again and again to see the losses that are permitted to go on, a great many times, because the newly married couples had not learned a better way. Well, we now have a book of almost 300 pages devoted to this very subject—*Domestic Economy; or, How to Make Hard Times Good, or Good Times Better*. Written by a physician of much experience. Just let me mention a few of the things it treats of. First, drinking-water; where to place the building; arrangement of the kitchen; doors and locks. (Oh dear me! how many times I have seen people annoyed by badly working locks and hinges! A great many times I have called for the sewing-machine oil-can, and have received smiling thanks when I showed them what just a single drop of oil would do. Sometimes with a sewing-machine screwdriver, the single turn of a screw would make every thing work nicely.) Well, let us go on. The book treats of where to buy; how to buy; wasting; good morals; education; how to care for the baby; cooking; going to school; what books to read; habits of industry; house-cleaning; recreation; rats and mice; time wasted; fuel; how to make a fire; clothing; dogs and cats; fleas and bedbugs; washing-day; broken furniture; springs and cisterns; good bread; soups; sugar; doctors; exercise; care of the body; accidents; contagion; water-closets, etc. The price of the book is \$1.00; but by buying a large lot at one time, we have been enabled to get them so we can sell them for just 60 cts. If wanted by mail, add 8 cts. extra for postage.

THE GAULT RASPBERRY.

Our creek-bottom ground has given us a thousand or more beautiful plants of the above variety. They are the strongest and finest of any thing in the way of a raspberry plant I ever saw in my life. Many of them have three or four large shoots just coming to the surface of the ground while I write. Now, I am not at liberty to sell these plants for less than 50 cts. each; but I am permitted to sell one plant to every subscriber to *GLEANINGS* for 25 cts. each, postpaid by mail, in a strong wooden box made expressly for mailing them securely. Or if any subscriber will get somebody else to subscribe we will send him a plant free; or whoever sends \$2.00 for *GLEANINGS* two years may have a plant free. Even if you have only the tiniest bit of garden, I think you should have one Gault raspberry-plant. They begin to bear when they are not much larger than a strawberry, and keep bearing right straight along until frost. Each plant will make you ten or a dozen plants next fall, and the prospect is they are going to be worth a good deal of money next year at this time. Without taking any special care, we have secured over a thousand nice strong plants from not quite a hundred plants last spring. The young plants will probably bear fruit this year, unless you pick the blossoms off. The berries are so very heavy they almost need mulching like strawberries to keep them out of the dirt, unless they are tied up to a stake or some sort of trellis. See cut and description on page 959, last year. Or we will mail you drawings from a photo, with full description of the new raspberry. A. I. R.

THE SEED AND PLANT BUSINESS BY APRIL 15.

On account of the late spring, and much frost remaining in the ground, the plant-trade is rather slow as yet; but the demand for seeds has been larger, perhaps, than in any other spring since we have been in the seed business. Onion-sets are still going down. We can offer nice Yellow Globe Danvers sets at 15 cts. per quart; 75 cts. per peck, or \$2.75 per bushel. Either White Victoria or Prize-taker, \$1.00 per peck or \$3.50 per bushel. White Multipliers, while they last, \$1.00 per peck, \$3.50 per bushel. Large-sized sets, $\frac{1}{2}$ above prices. If wanted by mail, add 10 cts. per quart for postage. By the way, the White Multiplier is the best onion to keep over winter of any thing we have come across. They are about as handsome as any onion in the world, and about as nice to eat. They never send up any seed stalks, but just keep right on multiplying; and if you gather the bulbs when the tops are dry, you can keep them without any trouble from sprouting or getting soft; and even where they have been repeatedly frozen, they stand it about the best of any onions I know of. The objection is, that they seldom get as large as other onions, and that they do not yield as many bushels per acre. I am inclined to think, however, that, with the right kind of soil and cultivation, the yield is going to be pretty satisfactory. You can plant them either in the fall or spring, as you choose. Our own, planted last fall, seem to have stood the winter with very little damage.

SEED POTATOES.

At the present writing we are sold out on Everett's Six Weeks, and second-size potatoes of all kinds except Monroe Seeding. We can furnish the latter at \$1.50 per barrel; or first size, \$2.50 per barrel. Early Ohio, Early Puritan, Lee's Favorite, Rural New-Yorker, \$1.50 per bushel or \$3.50 per barrel, so long as they hold out.

We have a nice supply of asparagus-roots, two years old, 75 cts. per 100, \$6.00 per 1000; one-year old, 50 cts. per 100, \$4.00 per 1000. The latter can be sent by mail for 25 cts. per 100.

At present writing we have a nice lot of both cold-frame and greenhouse cabbage-plants; ditto cauliflower. Onion and tomato plants are hardly ready yet to send out; but we have a splendid lot of White Plume celery-plants just right to ship. Saccaline and *Lathyrus sylvestris* have been pretty freely criticised by the press; but I feel sure the latter, at least, is worthy of trial. It has stood the severe winter without a bit of damage except to the greater part of the foliage. But they started out bright and green with the first warm weather; and when we come to dig up plants to ship, we find them going away down below any kind of clover; and the root is of such size that throwing out of the ground by frost would be almost an impossibility. During my recent visit with Pres. Clute he gave a very encouraging report of his experience with the plant at the Michigan Agricultural College. We can mail you a good strong plant for 5 cts.; saccaline, 20 cts.

DON'T SPRAY WHILE YOUR FRUIT-TREES ARE IN BLOSSOM.

On page 327 the Department of Agriculture says: "Don't spray trees when in bloom," but does not take space to give the reasons. First, it is not necessary; but second, and most important of all, it is liable to kill the bees and poison the honey if spraying is done while the trees are in blossom. Beekeepers are interested in having this matter well understood and emphasized, even if other people are not.

Kind Words From Our Customers.

BETTER THAN EXPECTED.

Dear Friend:—I want to send you a few words by way of thanks for your promptness in business. Why, sirs, a man can see the spirit of our blessed Savior in your work, and in your way of doing business. You say, "Did you get your goods all right?" Well, yes (if I know what is right); yes, every thing was even better than I expected, and I now send you another small order. W. H. BOX.
Russellville, Ala., Feb. 2.

[We try always to live up to the teachings of that Savior; but sometimes our efforts are greatly misconstrued.—Ed.]

Root's goods are always as represented, and we get what we send for. We can not keep house without GLEANINGS. H. BOSWORTH & SON.

Ford, O., Feb. 8.

I take pleasure in saying that the goods which I purchased from you last May were all first-class, every thing just as ordered, entirely satisfactory. I know that you shipped them promptly by the shipping-bill which you sent me.

East Farnham, P. Q., Dec. 28.

JOSHUA BULL.

I have received GLEANINGS regularly, which gives me much pleasure. I have read your A B C and Langstroth on the Honey-bee. I found wonders unfolding on every page. All praise to the patient investigation bestowed by the study of bees by the various authors, unfolding, as they do, the handiwork of the great Architect of the universe. All praise be to him. C. F. GARLAND.

Grose Vale, N. S. W., Oct. 2.

KIND WORDS NOTWITHSTANDING A REPORT DISCOURAGING.

I commenced the season with 120 colonies; took 300 lbs. honey, no increase. Prospects are not very encouraging for next year, but we (wife and I) intend to do our best, and trust God for results. I feel that, whatever success I have in bees or other business, I owe a good share of it to GLEANINGS, more especially to the Home talks. Fifteen years ago I had scarcely any thing; but by being faithful in "that which is least" I have been enabled to provide a home for a loving helpmeet, and now a third party has arrived on the scene—a little blue-eyed girl. We started out to give you a report on bees and honey, but some way home thoughts crowded in, and we felt like giving a glimpse of our home life. Go on with your Home talks, and success to you and yours. H. L. ROUSE.

Republic, Iowa, Dec. 14.

OUR RELIGIOUS LITERATURE AND ELECTRO-POISE.

At present writing there seem to be just four of our leading religious periodicals that are proof against the money that the Electropoise people offer. They are: *The Sunday-School Times*, *The Christian Advocate*, *The Independent*, and *The Advance*. If there are others, I should be glad to give them honorable mention. The temperance periodicals seem to be accepting the advertisements blindly; and, when called to order, the principal excuse I have been able to find is, that they are sadly in need of money. Not an agricultural paper in our land, so far as I can discover, has given them a single insertion. What sort of showing, dear friends, is this for temperance and religion and science? Dr. DePuy, of *The Christian Advocate*, who has been paraded so largely by the Electropoise people, severs his connection with that journal on the 1st of May. *Electricity* says:

"The Electropoise killed Dr. DePuy."

The same paper also says:

Not one medical man of standing, not one single scientist, can be found to indorse it. *Electricity* referred it to six of the leading electrical scientists of the country, and to a dozen of the leading physicians in New York City, every one of whom pronounced it an unqualified fraud.

"O CONSISTENCY!"

The following bright hit comes from our old friend the *Rural New-Yorker*:

Imagine a man teaching his pupils that whisky and tobacco are harmful, and then being caught by the boys, smoking a cigar on the sly!

Ernest remarks right here, that one of the best talks he ever heard on whisky and tobacco was given by a minister of the gospel who was afterward caught by the boys, smoking a cigar on the sly. There are a good many ministers of the gospel, as I happen to know, who take this journal. Dear friends, does the above searching suggestion hit you in any way?

A SURE INCLOSURE for sheep and hogs.

A RELIABLE PROTECTION against dogs for sheep.

A SATISFACTORY FENCE to property-owners along railroads.

A FENCE COMBINED for both large and small animals.

A COMPACT MATERIAL for portable corrals.

Excellent for grapevine trellises.

Animals will not bend it to crawl under or climb over, or loosen it from the posts.

"G & B" WEB-WIRE FENCING is made of the best quality **Heavy Galvanized Steel Wire** (No. 14 in the meshes, No. 13 in the selvages) woven into diamond-shape meshes by automatic machinery, insuring a regular and smooth fabric, strengthened by **three-strand rope selvages** at both sides.

The 3x6 inch mesh is suggested for sheep-enclosures; the 4 x 8 for cattle and hogs, and the 5x6 x 10 for a very low-priced fence for any purpose named.

PRICE IN FULL ROLLS, 20 RODS EACH.

3 x 6 inch Mesh.	4 x 8 inch Mesh.	5 1/2 x 10 1/2 inch Mesh.
WIDTH. PRICE.	WIDTH. PRICE.	WIDTH. PRICE.
26 in. Rod, 37 c	36 in. Rod, 31 c	28 in. Rod, 31 c
32 in. Rod, 45 c	42 in. Rod, 36 c	36 in. Rod, 31 c
38 in. Rod, 48 c	48 in. Rod, 42 c	47 in. Rod, 36 c
50 in. Rod, 58 c	50 in. Rod, 47 c	

All widths put up in bales 20 rods (330 feet) long.

A higher price charged for lengths shorter than a full bale. Shipped direct from Chicago or New York.

What we wish to call your attention to especially is the following list of pieces and short rolls which we can sell, to close them out, at *less than full-roll prices*. In this list are some full rolls and pieces of sizes which the factory have discontinued making, and for that reason they offer them at a sacrifice to clean up the stock of odds and ends.

The above, you notice, is woven from galvanized wire, while you will find the most of the following list is 4x7-inch mesh, galvanized after being woven, and on that account very much superior, and more expensive to make. It formerly sold for about double the prices named below. It has also one number heavier wire in the meshes than the rest, being No. 13 wire throughout. All other sizes are made of No. 14 galvanized wire, woven in the meshes, and a 3-strand rope of No. 13 wire for selvage, except the 4x8, which has No. 10 wire selvage.

The wide fencing is designed to be put up alone, while the narrow widths are used at the top or bottom in connection with barb-wire or other strand fencing. Much narrow is used at the bottom of posts for hogs and sheep, while for horses and cattle it is often used at the top of posts in place of a board or rail.

All the fencing in the list, except the last few lines, is in stock in Chicago and New York, and shipments will be made from these points. That you may know what is in stock at each place we have inclosed within brackets [] all the stock in New York; and what is not so inclosed is at Chicago. The length of the pieces is given in feet, and the price per foot as well as per rod. This fencing is usually sold by the rod; but for convenience in ascertaining the cost of each piece we have given also the price per running foot, and you have simply to multiply the combined length of the pieces you require by the price per foot to get the cost. We get an additional discount if ordered in lots of 10 pieces; and, therefore, if you can use so much you can secure this fence at a price which is below what new regular stock in above list costs us at wholesale. The freight from New York to Chicago in 100-lb. lots or more is only from 2 to 5 cts. per rod; so if any of our western customers desire some of

the New York stock they need not refrain from ordering on account of freight charges.

In the following table the width in inches is given in the first column; size of mesh in second; price per rod in third; price per linear foot in fourth, and a list of the pieces, with length in feet, in fifth.

Inches.	Price.	List of Pieces, and Length in Feet.
Wide Mesh	Rod Ft.	Multiply by price per foot for cost.
26	4 x 11	32 2 bales, 20 rods (330 ft.) each.

In lots of 5 pieces, 5% off. Not less than 10 pieces in one order, 15% off from above prices; 20 pieces or more, 20% off from prices in this last table only. Staples, 1 1/4 in., 5 cts. per lb.

WIRE NETTING.

SHORT ROLLS AT FULL-ROLL PRICES OR LESS.

We have the following lot of wire netting of various sizes and widths in short or odd-length rolls. Very often a person wants a piece and can not buy it cut from a full roll without paying double price. You may be able to find in this list just what you need, or very near it. Even if you want more than a full roll you will find the prices at which we offer these to be in most cases less than full-roll price.

Of 2-inch mesh No. 19 wire, we have the following remnants and short rolls at 1/2 c per square foot. The figures at the left give the width in inches, and the other figures give length of each piece in feet. Multiply this by the width in feet, then take one-half of the result to find the price of each piece.

18	138.
30	107, 107, 144, 146, 148.
36	40, 49, 53, 54, 54, 56, 67, 70, 73, 83, 83, 83, 86, 90, 90, 91, 92, 93, 94, 96, 96, 100, 100, 102, 102, 102, 107, 109, 116, 116, 116, 116, 118, 120, 122, 124, 124, 124, 125, 128, 129.
48	62, 83, 83, 94, 94, 95, 98, 98, 100, 108, 108, 112, 112, 113, 119, 122, 123, 124, 124, 125, 131, 132, 138, 138, 138, 140, 140, 140, 143, 144, 144, 145, 145, 145, 146, 146.
54	72, 88, 88, 143.
60	103, 110, 126, 134, 36, 139.
72	15, 27, 60, 61, 72, 85, 85, 87, 100, 119, 123, 130, 138, 142, 144, 144, 144.

Of 2 inch No. 20 we have the following pieces at one-half of a cent per square foot, less 10 per cent. Arrive at the price in precisely the same way as above, and take 10 per cent off.

30	1 79
36	48, 76, 81, 88, 100, 103, 103, 109, 116, 122, 126, 126, 128, 128, 128, 136, 140, 141, 144, 146, 146.
48	76, 116, 128, 144, 146.
54	145.
60	17, 113, 136, 139, 144, 144.
72	70, 139.

In the following list we give first the size of mesh; next, the number of wire; next, the width in inches; then the length in feet, and, finally, the price of the whole piece, so you will have no figuring to do.

2	in., No. 15, 18 in. x	75 ft., at 1.60; 18 in. x 74 ft. at \$1.55.
2	in., No. 15, 18 in. x	55 ft., at 1.20; 54 in. x 122 ft. at \$8.00.
2	in., No. 15, 60 in. x	20 ft., at 1.50; 72 in. x 36 ft., at \$3.00.
2	in., No. 15, 72 in. x	33 ft., at 3.00.
2	in., No. 16, 72 in. x	36 ft., at 2.3; 72 in. x 55 ft., at \$3.60.
2	in., No. 16, 72 in. x	55 ft., at 3.60.
3	in., No. 14, 72 in. x	70 ft., at 5.25; 72 in. x 100 ft., at \$7.50.
1 1/2	in., No. 19, 3 ft. x	129 ft., at 3.85.
1 1/2	in., No. 18, 4 1/2 ft. x	118 ft., at 6.35.
1 1/2	in., No. 19, 3 1/2 ft. x	85 ft., at 2.00; 4 x 55 ft. a' \$1.50.
4 1/2	x 20 ft. at 60; 5 x 19 ft. at 65; 6 x 44 ft. at \$1.90.	
1 1/2	-inch No. 18, 3 x 64 ft. at \$1.75.	
1 1/2	-inch No. 16, 3 x 5 1/2 ft. at .25; 2 1/2 x 70 ft. at \$3.00.	
4	x 24 ft. at \$1.65; 6 x 102 ft. at \$6.10.	

In lots of 5 pieces, any one or assorted kinds, deduct 5%; 10 pieces, 10%; 25 pieces or more, 15%. Better name a second or third choice, in case your first be gone. **The A. I. Root Co., Medina, O.**

HONEY COLUMN

CITY MARKETS.

KANSAS CITY.—*Honey.*—The stock of comb honey is large; market well supplied. Fancy white 1-lb. combs, 13; amber, 11. Receipts of extracted light; white, 7; amber, 5½@6; Southern, 4½@5. Beeswax, 22.

HAMLIN & BEARSS,
Kansas City, Mo.

April 18.

CHICAGO.—*Honey.*—We report our market well cleaned up on fancy white comb honey in 1-lb. sections. A neat package and a fancy article would sell quickly at 14c. No. 2 comb, or dark, would not sell at over 10@11. We report better inquiry for extracted, at 5@7, depending on quality. Beeswax selling at 30c.

S. T. FISH & CO.,

April 17.

189 South Water St., Chicago, Ill.

CINCINNATI.—*Honey.*—Demand is quiet for all kinds, with a fair supply only on the market. We quote comb honey at 12@14 cts. for best white. Extracted honey at 4@7, according to quality. Demand is good for beeswax, with a scant supply. It brings 25@31 cts. on arrival for good to choice yellow.

CHAS. F. MUTH & SON,
Cincinnati, O.

April 19.

CHICAGO.—*Honey.*—The supply of comb honey is very light, and it looks as though all would be sold unless it be some California that is being spread upon the street. Best grades of white comb, 14c; dark, 8@10. Extracted, 5½@7, as to quality, body, flavor, and package. Beeswax, 28@31.

R. A. BURNETT & CO.,

April 18.

163 So. Water St., Chicago, Ill.

BUFFALO.—*Honey.*—The demand for honey is very light; stock is getting well cleaned up, and there remain only a few tail ends unsold. Moderate sales of fancy, 13@14; choice, 11@12; other grades range from 7@9. Buckwheat honey moves very slowly here; would not advise any shipments. Extracted honey is also very quiet, ranging in price from 4@5. Beeswax, 25@29, according to quality.

BATTERSON & CO.,
Buffalo, N. Y.

April 17.

ALBANY.—*Honey.*—We have received quite a lot of comb honey during the past few days—one lot of paper cartons from Buffalo; but the weather begins to get warm, and the demand is falling off. We quote clover at 11@12; buckwheat, 8@10.

CHAS. McCULLOCH & CO.,

April 18.

Albany, N. Y.

PHILADELPHIA.—*Honey.*—The supply of comb honey is getting low, but there is correspondingly little call. Good white clover, some broken combs, sold at 9½c. We quote comb, 9½@12; extracted, 5@6. Beeswax, 31.

WM. A. SELSER,

April 18.

10 Vine St., Philadelphia, Pa.

BOSTON.—*Honey.*—Comb honey is in good demand, with a light supply; and, should present demand continue, we could get 14@15 for fancy white comb in 1-lb. sections.

E. E. BLAKE & CO.,

April 18.

Boston, Mass.

CLEVELAND.—*Honey.*—There is no material change in the prices of honey since our last report; if any thing, the demand is lighter. Strictly fancy No. 1 white is selling at 13c; No. 2, 11. The demand for extracted is livelier, and prices are from 6@8. Beeswax, 28@30.

WILLIAMS BROS.,

April 17.

80 & 82 Broadway, Cleveland, O.

DETROIT.—*Honey.*—Very little No. 1 white comb honey in this market, with fair prospect for selling out before new comes in. Extracted, 6@7; sales slow. Beeswax is in good demand at 30@31.

M. H. HUNT,

April 18.

Bell Branch, Mich.

DENVER.—*Honey.*—There is an improvement in our market for both comb and extracted honey. We quote No. 1 comb, in 1-lb. sections, at 11½@12½; No. 2, 9@10. Extracted, No. 1 white, in 60-lb. cans (2 in 1 case), 6@7. We are short on No. 1 comb, and could handle a quantity to advantage.

R. K. & J. C. FRISBEE,

April 20.

Denver, Col.

KANSAS CITY.—*Honey.*—The demand for comb honey is light; demand for extracted, good. We quote 1-lb. comb, No. 1 white, 14; No. 2, 12@13; No. 1 amber, 11@12; No. 2, 8@10; extracted, 5@6½. Beeswax, 22@25.

C. C. CLEMONS & CO.,
Kansas City, Mo.

April 18.

ST. LOUIS.—*Honey.*—We have fairly good trade in honey, and on account of early receipts of new crop expect an improvement. We quote comb, 10@13; extracted, in cans, 6½@7; in barrels, 5@5½. Prime beeswax scarce at 30½@31.

D. G. TUTT GROCER CO.,

St. Louis, Mo.

Apr. 18.

ALFALFA HONEY, very white, thick, and rich. Two 60-lb. cans at 7c. Same, partly from cleome (tinted), 6c. Samples, 8c.

OLIVER FOSTER, Las Animas, Col.

No. 1 extracted honey in 50-lb. pails at 7c per lb.—\$3.50.

J. B. MURRAY, Ada, O.

BUFFALO, N. Y. Unsurpassed Honey Market.
BATTERSON & CO. Responsible, Reliable,
Commission Merchants. 187rdab and Prompt.

High=GradeBicycles

ONLY \$60.00.

These are high-grade in every respect, both as to material and workmanship. We have personally tested them thoroughly, and know that they are first-class.

Tires, Morgan & Wright or Hartford single-tube pneumatic tires; wheels, 28-inch, wood rims; ball bearings throughout; pedals, rat-trap or rubber; handle-bars, raised or drop; frame of best quality of drawn seamless steel tubing; weight, 28 lbs. The entire bicycles are built by one of the largest bicycle works in the country. The extremely low price is owing to the fact that they are made on '94 machinery, and under another name-plate. We can furnish gentlemen's or Ladies' wheels at this price. Write for circular.

WANTED.—To exchange 100 8-frame hives, with comb, smokers, bee-escapes, 10-inch foundation-mill, shipping-cases, a general outfit of Root's supplies, for offers. **OSCAR KERNS, Cowgill, Mo.**

WANTED.—To exchange bee-keeping supplies for full colonies of pure Italian bees, or two and three frame nuclei. Send me prices and get my annual price list. **GEO. E. HILTON, Fremont, Mich.**

WANTED.—To exchange safety bicycle, 28-inch pneumatic, bees, queens, **B. P. ROCK, L. C. B. Leghorn and L. Brahma eggs, for honey or bee-supplies. CHAS. H. THIES, Steeleville, Ill.**

WANTED.—To exchange poultry and eggs (3 best kinds) for thin foundation, sections, shipping-cases, or new smokers. **D. F. LASHIER, Hooper, Broome Co., N. Y.**

WANTED.—To exchange warranted Italian queens bred from imported mothers, for poultry or eggs, nursery stock, seeds, or plants, or offers.
J. H. GARRISON, 6900 Bleecok Ave., St. Louis, Mo.

WANTED.—To exchange S. C. Brown Leghorn pullets, at 75c, and eggs from breeding-pens, at \$1, for pneumatic safety bicycle in good repair. **Write quick. G. D. CLAPP, Chatham, O.**

WANTED.—To exchange eggs from choice fowls and ducks, finest stock, for Italian queens.
LESLIE STEWART, Jefferson, N. Y.

WANTED.—To exchange second hand 60-lb. cans, in good condition (boxed); delivered at your station at 25c each, for worker combs, or white comb or extracted honey, crop of '95.
B. WALKER, Evart, Mich.

Black and Hybrid Queens For Sale.

A few first-class black and hybrid queens ready to ship; blacks, 25c; hybrids, 30c.

W. J. FOREHAND, Fort Deposit, Ala.

TESTED QUEENS

done to do away with swarming. If done early enough it is usually successful. It will be seen that the queens displaced by these young queens are never more than a year old; in fact, they are fine, tested, Italian queens, **RIGHT IN THEIR PRIME**; yet, in order that they may move off quickly, and thus make room for the untested queens, they will be sold for only **ONE DOLLAR**. Or I will send the **REVIEW** for 1895 and one of these queens for only \$1.75. For \$2.00 I will send the **REVIEW**, the queen, and the book "Advanced Bee Culture." If any prefer the young, laying queens from the South, they can have them instead of the tested queens, at the same price. A discount on large orders for untested queens. Say how many are wanted, and a price will be made. Orders can be filled as soon as it is warm enough to handle bees and ship queens with safety.

W. Z. HUTCHINSON, Flint, Mich.

STRAY STRAWS FROM DR. C. C. MILLER.

FOUL-BROOD CURE of McEvoy, says *B. B. J.*, was advocated by Shirach in 1769.

HONEY, applied outwardly, is reported in *B. B. J.* as a satisfactory cure for chilblains and chapped hands.

THE USUAL number of pages in *GLEANINGS* is eight more than usual, and this time sixteen. If that thing goes any farther I'll have to sit up all night to read *GLEANINGS*.

HOW MANY bright bee-keepers are coming to the surface as writers! [Yes, I've noticed that there were more lately. I am glad of it, because it infuses new blood into our literature.—ED.]

THE "LONG IDEA" hive, if I am not mistaken, was just as popular with Poppleton in Iowa as in Florida. This in reply to A. I. R.'s query on p. 320. [Then is it a question of locality, or of the man?—ED.]

A 12-FRAME HIVE is what Observer in *Progressive* says Ernest Root has "gone and done." How's that, Ernest? Have you been getting up a new hive so much on the sly that I haven't noticed it? [See Editorials.]

F. L. THOMPSON, in *A. B. J.*, wants bee-journals to be more like conventions in having pithy, good-natured discussions. Good idea. [That's so; but the editors must have the help of their contributors.—ED.]

BOARDS $\frac{3}{8}$ thick were tried by Ed. Goodrich, for hives. It was hard to keep them warm enough for brood-rearing in spring. In the fall, combs and bees were kept damp by the ready condensation of moisture.—*A. B. J.*

CAGING THE QUEEN at swarming and cutting out cells twice, as given by E. France, p. 304, is a good plan that I formerly practiced, only I freed the queen at the last cutting of cells instead of keeping her caged ten days longer. I believe you'd like that better, friend France. I learned the plan from Doolittle.

I SECOND the motion you make on p. 312, Mr. Editor, to try to get an appropriation from Washington for the N. A. B. K. A., and may be Canada could chip in too; but I don't see why that should make any less effort in each State.

THE NEBRASKA *Queen* has a warning from Prof. Bessey against sacaline. After growing roots obtained direct from Russia, and giving it a fair trial, he sums up his opinion in these words: "I am confident that it is a rank fraud." Alas! farewell, sacaline.

"HOW MUCH CONVENTION time should be given to essays?" is a query in *A. B. J.* One man wants the time all taken up with essays, "unless the discussions can be well managed;" two or three would rather have no essays, and nearly all agree that essays should be short, merely used to start discussion.

HONEY OR BUTTER? Dr. Peiro, in *A. B. J.*, says of honey, "Its nourishing properties are certainly equal to, and for many greater than, that of the best butter; and in view of the danger of butter from cows affected with tuberculosis he raises the question whether it would not be wise to substitute the perfectly safe article, honey."

DOOLITTLE is right, p. 313, that bees gnaw foundation whenever they're idle, but I've found it only at the close of the honey season, for the simple reason that they've had the chance only at that time. I've had to put on sections in advance of their need, for want of time later; but the bees are busy in the brood-chamber, and don't gnaw sections then.

BURNING SULPHUR made a yellow deposit for you, Mr. Editor, p. 317. I've had a few sections at different times discolored with sulphur, and it was always a greenish color. I suspect it makes a difference on what surface the deposit is made. [My "yellow" you might call a "greenish color." The difference, I suspect, is not in color but in the individual.—ED.]

FIGHT FAIR, friend Boardman. On page 294 you teach that a queen doesn't go into the super over a square hive; but that in the long shallow hive, queen-excluders and other ex-

pensive devices are needed. My queens are not hindered in any way from going into the supers, and it's a very rare thing for them to do so.—[Yes, reports seem to show that this is so.—ED.]

RAMBLER, p. 299, thinks bees don't sting hogs, on account of the smell. When rattlesnakes were plentiful here—I killed 11 my first summer in Illinois—hogs killed them, and I never heard of a hog being hurt by a rattler. It was said the snake couldn't bite through the hog's hide. Can a bee sting through it? Anyway, how much better than a sting would it be to smell like a hog?

HONEY FOR BABIES. "M. Forester Dietz has had his infant son, now aged seven months, reared entirely with the bottle which contained milk sweetened with honey. Has already consumed 25 lbs., is strong and plump, has never had a single pain, and sleeps soundly the whole night. At first the child received half milk and half honey liquefied with water; now he has four parts milk and one part honey liquefied with water."—*Bulletin d'Alsace-Lorraine*.

CHAPMAN HONEY-PLANT seed is offered free in *B. B. J.* Don't fool with any big quantity, friends. I suppose acres of it were planted in the U. S., and I believe it's the only honey-plant that the government ever furnished free to bee-keepers; but if there's a single man who now cares to occupy ground with it he is keeping very still about it. [The Chapman honey-plant was not a success in this country; but the bees make a great show on a single plant.—ED.]

RAILROADS in England have "agreed that bees in hives sent in truck-loads to the moors during the heather season, should be conveyed at 6d. per truck per mile, station to station, owner's risk, with a minimum charge of 7s. 6d."—*B. B. J.*, page 14. That means, if I understand rightly, that a carload of bees will be taken 40 miles for \$5.00. How much would it cost in this country? [Bees by freight go as third class. The rate on a carload of bees to Cleveland (about 40 miles) would be 10c, making the total freight \$20.00, or just four times as much as in England; and this, notwithstanding that railroad companies in the mother country pay enormous taxes in support of the government.—ED.]

Is JAKE SMITH a plagiarist? or have the people across the water been getting points from him? At any rate, that idea of measuring bees' tongues is having very serious attention in France. Actual measurements with ingenious glossometers show a great variation in the different colonies of the same apiary. By careful selection persistently followed up, why may not a permanent strain of red-clover bees be established? [If our queen-breeders would spend more time in developing a strain of red-clover bees and less to yellow bands it would be better for the honey-producer. We are

getting a large number of complaints from bee-keepers who have purchased the yellow stock. The past winter has shown that the majority of the colonies of this strain are practically good for nothing so far as hardness is concerned. As I have before said, the tendency is to sacrifice every thing for color. In a few rare instances, other good qualities are present. Yes, let's have long-tongued, long-lived, long-houred workers.—ED.]

FEEDING BEES.

DOES IT PAY? THE SUBJECT REVIEWED UNDER NEW SIDELIGHTS; A PRACTICAL ARTICLE FROM A PRACTICAL MAN.

By H. R. Boardman.

There are some kinds of feeding that pay well, and other kinds not so well, and some kinds not at all. I will try to show what kind of feeding pays, and how it pays, and what doesn't pay, and why.

After the honey season is past, if there are any light colonies in the yard that lack only winter stores to make them good promising colonies for another year, I am sure that the expense of a few pounds of sugar, and the trouble of feeding it, will be repaid with good interest unless such colonies are to be united to prevent increase. I don't think this will need the support of any very long arguments. It is often said, though, that there should be no light colonies at the close of the season, with good management. I wish I could manage so wisely; but I can not, and I am assured by the reports that others do not, so the need of feeding is apparent in this case. These late-fed colonies make the very best to winter, and for the next season if the work of feeding has been thorough. They should be fed enough to carry them not only through the winter, but through the early spring as well. The giving of liquid feed is more profitable in the fall than in the spring. The fall feeding gives young bees for winter. Spring feeding, by exciting the bees to activity, induces them to fly out, when they are chilled by the cold spring winds, and many will thus be lost at a time when there are no bees to be spared. It may induce robbing also, and much of their vitality will be spent in useless activity in marauding.

If colonies should be found light in early spring, there is one kind of feeding that I would always recommend. Place combs of sealed stores next to the brood-nest; and it pays to be provided with these for an emergency. Upon the first cost of the brood-nest depends very much the future value of the colony. The old bees are in sufficient force early to do the work

if they but have stores and a good queen; but not so later on.

When early pollen appears from the willows and maples, which is usually in the fore part of April in this locality, the queen gradually expands the brood-nest by laying around the outside until the first or earliest in the center of the combs begin to hatch, when she will return to the center and commence to refill the combs with eggs as the brood hatches. In the mean time the old bees fail rapidly, and there comes a time when the disappearance of the old bees gives the colony a very feeble appearance; and, indeed, it is a very critical time, and must be bridged over by the few young bees already hatched. A cold spell at this time is sometimes disastrous, although the sealed brood generates considerable warmth, which helps to protect the central brood-nest, which is now being filled with eggs.

It will be readily understood that feeding at this time would do very little good, and only imperil the colony by exposure to robbing. Many colonies will be so weak in workers as to refuse feed entirely. About the first of May the colonies will usually begin to build up rapidly from the hatching brood. At this time, or as soon after as the weather and the condition of the bees will warrant, the giving of liquid feed may be safely and profitably begun; and the brood raised from the stimulus of the feeding will furnish workers for the early honey-gathering. The natural pollen-supply is of much importance in connection with the feed, and should be carefully watched.

FEEDING UP TO THE SWARMING SEASON.

Feeding before the swarming season to supply winter stores is another kind of feeding that I have practiced with quite gratifying results for several years. It is expected that worker-bees, raised on honey for the honey-harvest, will more than pay the expense of raising them; but it is not very gratifying in a poor season to have only enough honey to raise them, and none to go into the surplus for the bee-keeper's share. By the time the surplus season begins (10th to 15th of June in this locality), the brood-combs will usually be exhausted of stores, or nearly so, and no work can be expected in the sections until these are filled to their utmost capacity; and the amount of the choicest honey of the season required for this purpose would be an important item if secured in the sections, especially in a poor season.

It occurred to me some years ago that sugar, exchanged for honey at the prices of the two, if the exchange could be economically effected, ought to be a good trade for the bee-keeper, and it is this kind of exchange that I have been trying to make with my bees by supplying them with sugar for winter stores before the honey season, and allowing them to put the honey into the sections for my share in return. The advantages of this plan are, it furnishes stores

for wintering the bees, that are unsurpassed by any gathered from natural sources. It answers at once for stimulative and store feeding. It keeps brood-rearing going without interruption from failure of the natural honey-yield. It takes the place of the same amount of honey that will be stored in the sections. I expect to commence feeding only moderately—just sufficient to stimulate brood-rearing and increase as the season advances, so that, at the beginning of the surplus season, the combs will be filled and sealed over outside of the brood-nest. It is hardly necessary to explain that these stores will not be used by the bees except in an emergency, but will remain for winter stores and for brood-rearing the following spring. I want the hives well filled with brood at the beginning of the surplus season—the more the better; and if all combs outside of the brood are occupied with sealed stores I should not expect to wait long for work to begin in the sections, provided the bees were gathering any honey; but the persistence with which they continue to store in the brood-combs at this time is often disappointing. But, “the best-laid plans of mice and men gang aft agley,” and this plan is not without its difficulties and perplexities. The prosperity of the bees under such generous treatment encourages swarming; and just as our plans may all be perfected the bees often upset them by introducing something of their own, and swarming out, leaving our well-filled hive and our well-laid plans for prospective surplus, to start business anew. Then we meet the same old difficulty—no more nor less than under the influence of a liberal honey-yield from the flowers. To get the full benefit of this plan, then, it is necessary to prevent swarming, or return the swarms; or if increase is desired, feed up the new colony.

I mention this difficulty, as it seems to be the most serious one in this plan. I think most practical bee-keepers would feel able to overcome this in some way. Almost every bee-keeper has a non-swarming remedy; but mine is—*young prolific queens*.

East Townsend, O.

[Mr. Boardman has made the subject of feeding a very careful and critical study for the last four or five years; and it is only now that he has reduced this valuable experience to writing. Of course, many of the veterans will say there is nothing new to say on the subject of feeding. In a certain sense that is true; but in another sense it is not true.

Regarding fall feeding, I might explain that I called on Mr. Boardman last summer, after the honey-flow, and he was feeding his bees with his entrance feeder, right along during the robbing season. The construction of the feeder is such that it is not necessary to open the hive, and almost impossible for robber-bees to get at the feed without going clear through the entrance, past the sentinels, and getting out again with their load *if they can*. At the time of my visit friend B. was not ready to have his feeder described; but now that he has it fully perfected he has consented to have it done, and

I take pleasure in showing you the illustration. A is an ordinary fruit-can, and B a special cover having a flange sticking up high enough so as to make what is known as an atmospheric feeder, on the Hains style. This is then inverted and set right down over a hole in a box so constructed as to fit closely to the entrance on one side. The points D D project clear in,

BOARDMAN'S FEEDER.

making it necessary for robber-bees, if perchance they are able to pass the guards, to go clear into the hive around D. It is altogether improbable a robber could accomplish her pesky meanness without being "caught in the act."

I have not been advised as to whether Mr. Boardman expects to sell these feeders; and while the main principle is old, the method of application is new. All together, he has, in my opinion, a *moral* right to the control of the sale.

I have examined a great many entrance feeders, but I do not know of any that seem to secure so perfectly the result as this does. Indeed, I never saw any thing yet attached to the entrance in the way of a feeder but that would make more or less of a hubbub in the apiary; but Mr. Boardman's bees at the time I visited his yard were as quiet and peaceable as if clover honey were coming in. This happy result I attribute largely to the projecting points D D.

In our next issue, Mr. Boardman will say something about feeding back, sugar honey, etc.—Ed.]

ARRANGEMENT OF BEE-FORCE.

THE BEST WAY TO STRENGTHEN WEAK COLONIES; A SEASONABLE ARTICLE.

By C. A. Hatch.

The success or failure of a commander of an army depends much on the arrangement and distribution of his forces. The part to be actively engaged must be placed so as to get

every advantage of position possible, and the reserve force must also receive proper attention and thought as to place and base of supplies.

Every bee-keeper occupies, in a certain measure, the position of commander of an army. The field-bees are his active forces; the nurse-bees and downy young ones are his reserve; the fields and forest his battle-ground which are to be robbed of their hoarded riches for the enhancement of the commander's interest. And no army ever proved more faithful, or adhered more closely to their chief's interest, than will this army of busy workers. But no commander's success depended on his arrangement and placing of his command more than does the bee-keeper's. Therein does he show his skill. If it were otherwise, any one could succeed in bee-keeping; for all there would be to it would be the possessing of the bee-force, and the bees would do the rest: whereas this force must be guided and directed, even as much as the army must be commanded, to be successful. Weak battalions must be strengthened; strong battalions must support and help the weak. The above is only a prelude, to borrow a musical term, to the real object of this article; but the fancying myself a commander-in-chief pleased me and may others; perhaps it tickles my bump of self-esteem.

WEAK BATTALIONS.

What to do with weak colonies in the spring is one of the ever-recurring problems that come before the bee-keeper. The old maxim, "Keep all colonies strong," may be true enough as a general principle, but it will hardly apply here; and trying to make it apply has ruined what might have been a fair colony for profit at the close of the honey season; for to do this (make them strong) only two ways present themselves—to build them up with brood from those already strong, or put several together, and thus make one strong at the expense of several. In following the first method, you have not increased your bees any, only put your forces in a new position, thereby weakening the battalion that was none too strong, and putting the force subtracted where its only use is to support the poverty of its adopted home, without any serious results as to alleviating it.

If the other course is followed, you have destroyed at least half of your recruiting force by destroying the queens of those united with the others; and, furthermore, the chances are largely in favor of your united colony being no stronger at the end of two weeks than any one of them was at the beginning. It is well to bear in mind that all the bees brought out in the spring are old, and their term of usefulness is limited to days or weeks at the furthest, and no amount of uniting will save them from this fatality. One hundred bees in one hive will die just as soon when their time has come, as they would in ten hives.

THE CAUSE OF WEAKNESS.

This is first to be inquired into. Usually the queen is at the bottom of the trouble, but not always. She may be a drone-layer by reason of age or having passed her time of usefulness, or by reason of being raised too late in the fall before to meet the drones. In either case the only course is for the apiarist to destroy her and give her bees to some other colony. Other queens may be all right, but able to lay only a small quantity of eggs in a day. It is of this kind that you will probably find most, and here the former treatment would be suicidal. Simply let them remain; tuck them up close with enamel cloth and quilt, or division-board; see that they have plenty of honey, and do not disturb them until about ten days before clover-bloom, except to see that the queen has room to lay at all times. At this time, if you have observed the proper conditions as to food and warmth, each colony will have increased perhaps from three to five frames. These, if left to themselves, would, of course, not amount to much as honey-colonies in their present shape, for it would take about all the bee-force to maintain the heat of the hive, etc.; but I find that, by uniting the working force, we can get, even from this unpromising material, some surplus. First, look your colonies over and ascertain just how many frames of brood there are in each, and mark them in some conspicuous place with that number, selecting the best for your honey-colonies; then from the others take frames of sealed brood with adhering bees, and fill these honey colonies full of brood, putting the removed frames into the colonies from which the brood was taken. Just how many to leave in the robbed colonies will depend much on the weather at the time; if warm and fine, all but the eggs and unsealed brood may be taken, for there will be returning bees enough to care for them. Of course, it hardly seems necessary to say, "Do not carry away the queen, and mix the bees well in their new home." This is easily done by mixing the frames from different hives, not putting two from the same hive side by side. With this plan I have never found it necessary to cage the queen. By this plan, you have not increased your bees by one; but you have put them where they can do your work better, and their own housework will not suffer materially.

You have now quite a number of fighting battalions ready for the coming onslaught of forest, field, and plain; whereas, by building up the weak from the strong, only weak forces would have been at your command, and the spoils would have been few and scanty.

But the war is not over yet. You have these few weak colonies yet to care for. What shall we do with them? They will have increased some by the time swarming commences, and are worth looking after.

SWARMS.

These will probably come from your strong

colonies very soon after honey commences to come in, and then is the time to show your generalship again. Remember that increase of number of hives containing bees is not necessarily an increase of bees. Our maxim now should be: Allow no increase until all hives now occupied are *full*. Having this always in mind, one can readily see how to arrange those weak forces. Allow the swarms to issue in the good old way, which, in my mind, has no equal; hive them on their old stand, which is a small job if you have the queen clipped, as you should. Give them a new hive with two frames of unsealed brood, taken from the old hive, in it, and fill out with empty combs, foundation, or empty frames, as experience or conditions dictate as best; put a surplus arrangement on top, and your honey-gathering goes merrily on at the old stand in the old way, but with added vim. Take your eight frames of brood, which you have left from the old colony, and put them in two or more of your weak colonies, and by the time basswood blooms they are weak no more. If you think the queen is poor, and would rather replace her, all you have to do is to decapitate her majesty and put a frame containing a queen-cell in the hive, and you soon have a new queen to reign over your new colony.

After all colonies are made strong in this way, and if swarming continues, you can get all the increase desired by making nuclei of the brood instead of putting it in other colonies. This plan has been the one I have followed for several years, and can yet see no reason for change.

Ithaca, Wis.

[Here is another article on the same subject.—Ed.]

MANUM IN THE APIARY.

SPRING MANAGEMENT; JONES TAKES ANOTHER LESSON.

By A. E. Manum.

"Manum, do you run a hot-bed with all the rest?"

"No, Jones; this is what gardeners call a cold-frame. For the want of a better place, such as a hot-bed or a greenhouse, I start my plants in the house, and then transplant them into these little three-inch pots, and on sods, and set these in the cold frame."

"Do you expect those cucumber and melon plants to thrive when put out in the open garden?"

Oh! yes, if they are not put out too early, by growing them in pots and on sod they can be transplanted without disturbing the roots in the least; in fact, they never seem to stop growing when put out if kept watered. Now, Jones, we will see how the bees are prospering. We will make short work of it to-day, as the middle of April is pretty early to expose the brood-nest very long to the cool air. We can only look after their store of honey, and see how they are

prospering in the way of brood-rearing. There, this colony has some brood in four combs, equal to two full combs. Pretty good for this time of year!"

"Now, Manum, I get a little confused in calculating the amount of brood or honey in your hive when reckoned by frames. You see, I use the Langstroth size, while you use the Bristol frame, which is much smaller than mine. Now, what portion of my combs would be occupied by the amount of brood contained in two of your combs?"

"That depends somewhat upon the comb surface in the L. frame, since it varies somewhat, owing to the varying thicknesses of top and side bars. There is in one of my frames 114 inches of comb surface, while an L. frame has about 151 inches, making 37 inches more in the L. frame than in mine. The comb surface in 9 L. frames just about equals that in 12 of my frames, so that it takes nearly $2\frac{2}{3}$ of my frames to equal 2 of yours. Here is a colony that was strong in bees when we opened them last week, and just see how they have dwindled down. Oh! I see—the queen is a cripple. She can but just drag about; and see! there is a dent on her back. She has been caught in a tight place somewhere, to have met with such an accident. Well, I might as well break up this colony at once. What few bees there are I will unite with that light colony over on the other row. The queen I will drop down here and put my big foot on her. That makes one more colony to be numbered among the dead."

"Why couldn't you use these bees for a nucleus for queen-rearing, and save the breaking-up of a colony later on, as you spoke of this morning?"

"It is altogether too early in the season for that, Jones. I never think of forming nuclei before the 15th of May, and then only a few. I form the greater part of them after the first of June; because, of late years, the most of my orders for queens are for yearlings, which I commence to ship about the first week in June; and, furthermore, such bees as these would be nearly worthless for queen-rearing, as there are so very few young bees among them. You see they are all old settlers, and would be short-lived at best. In fact, I do not suppose they are even worth the bother of uniting with other bees; but I will unite them just for the sake of showing you how I do it. Now, there are just about bees enough here to cover three of my combs, hence we will remove all but three combs, and close the hive for thirty minutes or so, and in the mean time we will transfer two good colonies from my hives into these little experimental non-swarmer hives; and as the season advances we will watch their progress. Now we will unite those bees. First, I will remove three combs from the light colony, from near the cluster, leaving one comb of honey close to the cluster, and now I will place the three

combs, with the queenless bees, next to this honey, and the job is done. You will observe that this comb of honey between the two lots of bees keeps them separated until they become better acquainted, or all of the same scent, and then they will unite of their own accord."

"Manum, I see on this next hive a blue stick tacked on the front gable end. What does that indicate?"

"That indicates that the queen in that hive is one selected last fall for a breeding-queen; that is the way I mark them, so that, when I am in a hurry, I can go right to one of these hives without having to refer to my book. We will open up this hive and see what is in it.

"Goodness! this is a strong colony; see the brood! Why, they will swarm in two weeks, I should judge by the strength of the colony.

"Yes, this is a good queen; just see how large and plump she is, and how large and strong appearing her bees are. I am tempted to *steal* a comb of hatching brood from this colony and give it to that light colony, to which we gave the queenless bees. It would help them wonderfully—much more than those old bees will. Yes, I will do it, although it is too early for such work; but this colony can well spare the brood. The only fear I have is, that the light colony may not be able to care for the extra brood. But I will heat a brick and put it into the unoccupied half of the hive every night and morning, for a few days, and I think there will be no loss of brood."

Our Symposium.

THE LARGE OR THE SMALL HIVE.

LARGEST YIELDS FOUR TIMES OUT OF FIVE FROM THE LARGE HIVE; NOT A QUESTION OF LOCALITY; A STRONG ARTICLE.

By J. A. Nash.

I have read with much interest many of the articles on the hive question, but did not intend to say any thing myself, until the editor remarked that the subject was *still* open; then I concluded to say a few words.

In a number of the articles on this subject, the writers speak of a large hive for one locality, and a smaller one for another. Mr. Editor, is there so *very* much in this? I have been interested in bees since I was a boy; have kept them for the money there was in them, as well as the keen enjoyment I derived from a study of their habits; and in the years that are gone, when the flowers of our Iowa prairies and groves secreted honey, I believe I secured my share of it. Now, if the experience of over a quarter of a century has taught me one thing more thoroughly than another, it is this: While you can keep a small colony in a large hive, it is another matter altogether to have a large booming colony in a small one; and that a small

hive can be depended on to take the swarming fever altogether too often for the good of its owner's purse, if he wants a large yield of surplus honey. Were I depending on the sale of bees for an income, I would take the smaller hive every time. My largest yields of honey have come, four times out of five, from the large hives.

For many years I have produced extracted honey; but before the extractor came into general use I made shallow frames, about five or six inches deep, for supers on the Langstroth hive. These frames had a pair of vertical center-pieces nailed in. I would remove the filled frames, and saw them apart in the center, thus making a very salable package. Sawing off the top and bottom bar in the middle, leaving the center-piece as an end, I crated about 25 or 30 lbs. in a neatly dressed basswood box, and sold at a good figure, wholesale, to the merchants in the city, besides supplying many private families. But I digress. Much of this honey was stored in L. hives of 12 and 14 frames each. Our locality was good, and the yield from the large hives noticeably greater than that of some 25 or 30 hives, ten-frame L. size, but only six inches in depth.

On the road to one of my out-apiaries, years ago lived a bee-keeper of the old school. His apiary was composed entirely of basswood "gums," worked out thin and raised up from the bottom-board by flat stones about one inch thick. The capacity of these "gums" was, as their owner assured me, "purty nigh a half salt-barrel." To obtain surplus, he bored holes in the cover, and placed another large hollow log over the first, and in this way he often obtained large quantities of honey. I purchased ten first swarms of him one year, paying him \$60.00 cash for them (remember this was years ago, when bees were very high). They were very large fine swarms; were hived on empty frames (twelve-frame L. hive), yet I sold from these ten colonies over 400 lbs. of surplus honey at 24 cents per lb.

Some 50 or 60 rods down the stream lived another bee-keeper, a widow. Her bees were in box hives, as nearly as I can remember, 10x12 inches, and 13 inches deep. I am very certain in regard to the depth, as she assured me that 13 was considered an unlucky number; but she did not believe in luck at all—at least, *ill* luck. I left here 20 hives. Mrs. W. filled them with the swarms that issued in great plenty from her small hives. I paid this bee-lady \$80.00 for the 20 swarms, she readily admitting that Mr. K.'s swarms were worth more than hers. In the fall I found two or three of these swarms too light and weak to winter, and one colony had stored a little surplus.

Now, the net results of my bee operations have been something like the above with variations; and as I look back over the past, I find that with me the large hive, the large colony, and

the large surplus, have traveled hand in hand irrespective of good or bad location. Two good men can do twice as much work in a day as one; two good teams will accomplish twice as much plowing in a day as one; and a swarm that, when shaken from the tree, will weigh from 18 to 28 lbs. will just as certainly gather more honey than one that tips the scale at only half that amount.

Some ten years ago I concluded I was using hives that were too large, and, moving to a new location (the present one), I made all my new hives to take ten frames 12x12. Of these I now have about 100, bee-spaced, loose bottom-board, flat cleated cover, and a movable side. On these hives I tiered up half-depth bodies, filled with empty honey-combs. I soon found, however, that my ten frames would not do for a twelve or fourteen frame queen, so nearly all my colonies have an extracting-case of ten half-depth combs *under* the brood-chamber proper, which I seldom disturb, unless it is to take it, with adhering bees, to build up some weak colony, in which case another empty super takes its place.

For the edification of those who think that eight L. frames are plenty for a queen to occupy, I will say that I have often found this brood-chamber of ten large and ten small frames well filled with brood in all stages of development, and the queen looking for room to lay.

I have no red-clover queens, and, as yet, no five-banders or golden honey queens—just plain, every-day leather-colored Italians and a few hybrids.

I believe some one said that this kind of high-pressure brood-rearing is a trifle wearing on the queen, and causes her to come to an untimely end. Such may be the case; but when I find one that can't fill more than six or eight frames, I step on her and put a better one in her place.

I don't believe my bees are the best in the world; but I do believe in breeding from the largest and most prolific, and the best honey-gatherers. I keep a record of each hive; and when I find one that has had as good a chance as the rest, and doesn't make as much honey as it should, that colony gets a new queen. Of course, this is written mostly from an extracted-honey point; but were I producing comb honey, I should want a large colony.

I must agree with Mr. Boardman (our hives are much alike) in regard to the square hive for practical utility—page 250—for brood-rearing and wintering.

Monroe, Iowa.

[Say, friend Nash, did you ever try two eight-frames, one on top of the other? You have given some strong points in favor of large hives; now let some other fellow who thinks differently produce counter-evidence if he can; but, hold! here is another one right in the same strain from Mr. Doane.—Ed.]

SIXTEEN-FRAME HIVES A SUCCESS.

I commenced using 16-frame hives seven years ago this season. I made only one, as I was afraid. This colony is alive and in good shape yet. Four of the years it has given from 140 to 180 lbs. of comb honey. Two years they swarmed, when the parent stock gave about 60 lbs. one season, and 90 the other. One year they superseded the old queen, but didn't swarm. After trying this size of hive two years, I made some twelve or fifteen of them; and, as they gave like good results, I continued to add to the number of large ones in the yard, until I have now some thirty of them. I have the eight and ten frame, and have used them for twenty years; but I expect to put all in large hives this spring, as I get an average of nearly, if not quite, double as much from the large hives as from the small ones. Last season my best, in eight-frame hive, gave only about 60 lbs., while my best in the large hive gave 220 1¼ sections well filled, and 28 sections, same size, of No. 2 honey. If it would interest you to know more about these, and how I manage them, I will tell you.

I have 60-lb. cans ready to ship the honey in. If you should not want this honey, I will send you comb honey in its season. I have got raspberry honey off the latter part of June for several seasons.

I have just received one of your Cowan two-frame extractors from W. D. Soper.

Breckenridge, Mich., Apr. 6. N. E. DOANE.

[Although Mr. D. does not say so in just so many words, I assume that the 16 frames are all in one hive-body. The facts he gives are interesting. Can we not have more of them? Of course, we should be glad to hear from Mr. Doane further. Here is another:]

IN FAVOR OF THE TEN-FRAME HIVE.

I have 300 colonies on summer stands, some 200 with flat covers, and 100 with gable covers, all two-story ten-frame Simplicity hives. I have been very much interested in the eight vs. ten frame hive discussion. I have never used the eight-frame hive; have used the American pattern and discarded it. I think the ten-frame has advantages in this locality over the smaller hives. By their use we can build up to enormous colonies, and at the same time keep down swarming to a great extent. The natural swarms in my yards last season were 12 per cent. I use a two-story brood-nest, and often have sixteen frames of brood in the same. I run exclusively for extracted honey, so I have a less number of hives to visit for the same number of frames of honey, which is a great saving in labor. I would rather increase than diminish the size, by tiering up to three stories. I have used three stories to some extent, and find they give perfect satisfaction in my locality. I find that, by using eight frames in the extracting-supers, I am bothered less with brood in them. The cells being so deep, the

queen doesn't use them for brood unless they are cut down by the bees. My crop for the last season was ten tons of extracted honey from 270 colonies, spring count. Z. S. WEAVER.

Courtney, Texas, Feb. 14.

[And here is still another:]

You can put me down as being in favor of the large hive. I have about eight in ten-frame hives, and they have, strange to say, done all the swarming, and are the strongest colonies that I have. During my three years' experience with bees I have noticed that the ten-frame hives were ready for the extractor before any other, and after this season I expect to use no other.

Columbia, Miss.

T. S. FORD.

THE EIGHT-FRAME LARGE ENOUGH.

In regard to the size of hives, I will say the eight-frame Dovetailed hive is large enough for me. In the past five years I have transferred perhaps a hundred colonies from larger as well as smaller hives than the dovetailed, and put them into the latter hive, and all appear to be well satisfied with the change. I find it large enough for an average queen; and when we get at the average, we are then as far as we should go.

[Friend Pratt has hardly a fair show. Who will help him out?—ED.]

WINTERING.

WHY BEES CAN STAND LOWER TEMPERATURES OUTDOORS THAN IN THE CELLAR.

By Dr. C. C. Miller.

Dr. Miller:—Having been a reader of GLEANINGS for four years, and studied the A B C of Bee Culture for nearly the same length of time, I have a question to ask, something like this: I have several colonies of bees in single-walled Dovetailed hives, and they have been wintered outdoors for three years in Southern Iowa. My plan was to move them up side by side, and about four inches apart, then pack with chaff in between, also put on a Hill device and a chaff cushion on top of that. Now comes the most important part of my question. Bees, even when packed in this shape, will freeze some. Now, why will it hurt if they freeze some in the cellar, providing the bottoms are left on the hives? For the life of me I can not see where the difference comes in. Of course, I presume there is some difference; and if so, please show us where it is.

I am thinking some of erecting a sod house for my bees next winter. The walls will be two feet thick, with hay for a roof. Now, please tell us what you would think of my sod house. Supposing they get a little cool in it, what worse will they be than if they got a little cool or cold outside? This winter I have moved my bees out to Northern Nebraska, and have

packed them as before stated, except they are packed in moss. We have moss that is three inches thick, and we cut out our cushions with the hay-knife to fit the upper stories; also to go in between the hives. Please say how you think moss will do as packing. I know the bees are well packed, but I also know they are in single-walled hives; and I know that, on the morning of Feb. 6th, the thermometer stood 10° below zero; and on the 7th, 23° below; and on the 8th, 20° below.

Now, friend Miller, I know this is quite lengthy, but I hope you will give it your attention, and oblige.

JAS. PRATT.

Bartlett, Wheeler Co., Neb.

[Dr. Miller replies:]

Friend Pratt:—I must confess that your question is a little too much for me. I've asked that question myself more than once, and never got an answer entirely satisfactory. When bees are in the cellar, if the thermometer goes down to 38° we are told it has reached the danger-point. But if they are outdoors, and the thermometer goes down to 15 or 20, or even if it occasionally reaches zero, we think it's all right. It is so generally conceded that there is a big difference whether the bees are out or in, that you wisely refrain from disputing it, and I suppose it must be true; but then comes your troublesome question, "Why?" I may as well say at once "I don't know," and be done with it; but really it's such an important matter that it seems we ought to be able to get some light on it. For if we knew *why* bees can't stand the cold in the cellar that they can outdoors, then we might possibly be able to supply the conditions in the cellar that will enable us to winter the same as outdoors.

In the hope, then, that, by a discussion of the matter, some light may be drawn out from some quarter, "I'll mention some of the things that have at one time or another been thought to have a bearing. Perhaps the majority who have any opinion at all on the subject would say something like this: "The trouble with the cellar is the long confinement. Bees outdoors have an occasional fly, while at such times bees in the cellar must remain in the hives." It seems there ought to be some truth in that, for we know very well that in the spring a colony standing outdoors affected with diarrhea will often succumb if the spring is long and cold, giving the bees no chance whatever to fly; whereas, if a single warm day comes, giving them a good cleansing flight, they're then ready for another long pull.

If that's the right view, then, in few words, bees have a chance for flights outdoors that bees in the cellar don't have. How shall we meet this difficulty? It seems quite plain—carry out the bees for a flight every time those outdoors fly, and then carry them into the cellar again. Other things being equal, the cellared

bees ought to come out best in the spring if they are thus carried out, for they have a milder winter; and I think we all know that, the milder the winter, the better for the bees.

Just at this point, a friend at my elbow says, "Yes, that would be a lovely job, to carry the bees out and in every day they can fly!"

"Never mind the lovely job," I said; "if we can make them winter perfectly in that way it might pay."

"But they wouldn't winter well that way. It would stir them up every time they had a fly, making them uneasy, and they wouldn't be contented to stay in after they had been out. I don't believe it would be a good way at all."

And she spoke with such earnestness that I think she had some fear lest I should contemplate carrying out bees every mild day, as part of the regular program.

"But," I said, "the bees outdoors fly without disastrous consequences, and we don't try to keep them in the hives for fear they become uneasy; why isn't it the same in one case as the other?"

"They're not shut up—they're not shut in—they can fly when they want to."

"Why, they're shut up just as much in one case as in the other. Indeed, if there's any difference it's in favor of the cellar bees; for, on the whole, they're the warmer, and the cellar bees can fly when they want to just as much as the others, if we carry them out every time it's warm enough."

Silence was the only reply to this for some time; and then, woman-like, she turned on me with the remark, "Well, if that's the best way, why don't you make a practice of carrying them out and in? I don't think it is a good way."

I think it is generally agreed that it is not a good plan to carry bees out of the cellar until they are ready to stay out, and I think the idea is correct; but I confess I'd like to know why. Who can tell?

If, then, it's true that, by letting them have the same flights that they would have outdoors, they still can not stand the same cold, we come back to the old question, "Why?" Is it an occasional warming-up that they get outdoors, not enough for a fly, but still warmer than in the cellar? G. W. Demaree advocates occasional raising of the temperature in the cellar, and the plan looks reasonable; but after trying it one winter, I have less faith in it. Possibly it may be all right in Kentucky.

The only thing I can think of as a possible explanation is the difference in the air. Mind you, I don't know about it, but I'm searching for a clew that seems to give a little promise. I know we are told that bees don't need air; that you can get plenty for their use through a stone wall, and all that sort of thing. I don't believe a word of it. I feel sure they need some air, and I believe they're better off to have plenty

of it; and the purer the better. Do you think the air of a cellar averages as pure as that outdoors? Do you think a person who lives in a cellar is as strong and healthy as one living outdoors, even supposing one had the same light as the other?

I believe it is a well-known fact, although not so universally known as it should be, that, in a room where the air is close and impure, the thermometer must stand higher to keep the human occupants warm than in a room with fresh pure air. Is it not reasonable to suppose it may be the same way with the bees?

I'll tell you one thing that I have already mentioned, and I have noticed it many times. Along toward spring there come warm spells when the air outdoors is as warm as or warmer than it is in the cellar. The bees become very uneasy and noisy. At night I open up doors and windows, letting in a flood of fresh air. The noise in the cellar increases threefold; but by morning all is quiet, and sometimes the full light may stream in on the hives through the forenoon without their stirring out. It isn't because they are cooled off, for the thermometer in the cellar has gone up. Moreover, I have sometimes accomplished the same purpose by putting a fire in the cellar. You see, in the cold weather the heavy cold air from the outside forces its way in; but when the air in the cellar is as cold as or colder than outdoors, then ventilation stops, and the air becomes foul. The point is, that the bees are uncomfortable, and hence inclined to disease when the air in the cellar is more impure than usual.

Now, I don't know that the impure air is the whole reason why bees in the cellar must be kept warmer than outdoors; but I suspect it has much to do with it, and I'm ready for any light that comes.

The moss you speak of is, I suppose, sphagnum or nurseryman's moss, and is highly esteemed in Germany. I think you will like it.

Marengo, Ill.

WAX.

A DESCRIPTION OF THE PRINCIPAL KINDS, AND THE USES TO WHICH THEY ARE APPLIED; SUBSTITUTES FOR BEESWAX.

By Karl Rudolph Matthey.

[In presenting the following papers on the subject of wax, we believe we are giving our readers much of value and interest. The author, Mr. Matthey, who is now one of the staff of workers here at the Home of the Honey-bees, has written considerable for our columns during the last year or two. He has paid particular attention to the subject of wax, and appears to be unusually well informed in regard to it. He has quite a nice little library devoted to that subject, all in German, as that is the only language he uses here, and the one in which he writes his articles. The interest belonging to the subject will increase as the articles appear.—ED.]

Honey and wax—two natural products which, in their pure state, are obtainable from bees only—have, from the earliest dawn of human history, played a *role* of the highest importance in human economy. The Bible mentions milk and honey as typical of all earthly blessings. The Greeks and Romans flavored their wine with honey; the ancient Germans prepared their intoxicating mead from it; and in a time when men had neither sugar nor syrup, honey served exclusively as a sweet for their food and drinks.

Wax, on the other hand, was the only illuminating material for God's house and for palaces; and it found special application for pharmaceutical purposes; and for thousands of years the product of the bee had no competitor.

But now this is all different. A whole list of fats, partly from the animal kingdom, partly from the vegetable kingdom, and some (at least apparently) coming from the mineral kingdom, are, with the help of modern science, chemistry, and other adequate agencies, so manipulated as to resemble pure beeswax to such an extent as to be very deceptive. Yea, so well is this work done, that, for certain practical purposes, such as illumination, etc., the compound may be considered as perfect.

As these species of artificial wax, such as ceresin, paraffine, ozokerite, and all such mentionable products of human manufacture, can be, for the most part, furnished at an insignificant price, it follows, as a natural consequence, that pure beeswax must become greatly depressed in price to meet the price of the others. We get now hardly as much money for two pounds of beeswax as we formerly did for one.

Wax was already known in the earliest antiquity. The Greeks and Phenicians were acquainted with its use, and knew how to bleach it. Pliny called white wax "*cera Punica*" (Phenician wax); he describes the framework upon which the sheets were laid to bleach; and he even describes the cloths with which the frames were protected and the wax covered during unfavorable weather.

In the time of Dioscoroides, sheeted wax was known. The bottom of a pot was first dipped in cold water and then in melted wax; or a globe, likewise moistened, was dipped in wax. The sheets, or films, when removed, were strung on threads so they would not touch each other; and after copious washings they were set in the sun. At that time, illuminating material prepared from pure beeswax brought a high price. It was used in divine worship, and its consumption increased in proportion to the spread of Christianity. Even to-day the Mohammedans use wax tapers in their mosques. I saw such in the Aya Sophia, in Constantinople, at the right and left of the *mimrab* (prayer-niche), each taper being about 19 inches thick and 13 feet long. A similar one was in the mosque of the Sultan Achmet.

In former years, wax-bleaching was carried on as an independent business; and its extension may be inferred from the fact that, at the end of the seventeenth century, there were fourteen wax-bleaching establishments in Hamburg. In fact, except oil and tallow, and the inevitable pine shavings, no illuminating material was known but wax; and this, only the rich could use. At that time, even princes who indulged in this luxury (according to the conception of those times) were held to be spend-thrifts. Besides for candles, wax had a further use in the manufacture of artificial flowers and fruits, which were used as room ornaments, for at that time the use of sealing-wax and other kinds, for that purpose, was not known.

Besides beeswax we are now familiar with a list of vegetable fats which more or less resemble it, known by the common name of vegetable or plant wax; in addition to which has been recently added mineral wax—ozokerite—which, when refined, is known as ceresin, which is used to a great extent in the adulteration of beeswax.

Wax is still used nowadays for illuminating-purposes in divine worship, not only by Christians but by Jews. But the Orthodox Greek Church makes the most conspicuous use of it. It serves, also, for a number of technical, medicinal, and artificial purposes; and in spite of the diminished production of wax candles, beeswax alone will not supply the need of wax, as the different kinds mentioned allow of a wide use of that substance.

Continued.

T SUPER VS. SECTION-HOLDER SURPLUS ARRANGEMENT.

WHY THE A. I. ROOT CO. RECOMMEND THE LATTER.

By Dr. C. C. Miller.

A question is asked me on p. 215 that I shall be glad to answer as well as I can. It is about T tins; but in introducing the question a statement is made, or at least implied, over which I have pondered—"So few, comparatively, use T tins now." Now see, Mr. Editor, whether I give an entirely fair paraphrase of what you meant to express. "There was a time when T tins were much used, but not now. Section-holders are better than T supers, and are now taking the place of the latter." I should really like to know just how much truth there is in that. Are T supers less used than formerly? Can you give us the names of practical honey-producers who have thrown aside T supers for section-holders?

You may say that you know section-holders are taking or have taken the place of T supers, because you now sell many section-holders and scarcely any T supers. If you should tell me that about different kinds of sections, I should at once see the weight of the argument, for it would tell me about the preferences of bee-

keepers in general; for bee-keepers who use sections are continually buying new ones. But those who use T supers do not need to buy new ones, and so their lack of buying doesn't prove they think any less of T supers than they did. I don't expect to buy another T super as long as I live; but my not buying them doesn't prove anything about my preference. Now, if you say to me, "We sell a great many section-holders to those who have used T supers and have cast them aside," I shall, in all fairness, have to admit that, for such persons, with their present knowledge, section-holders are preferable.

But who are the purchasers? As surplus-honey arrangements last a long time, a large portion of the purchasers will be beginners. The beginner looks to you for guidance; and you say, in very plain print, "We consider the section-holder arrangement for holding sections on the hive superior to any other." That settles it for him, and you take his purchase as a proof that section-holders are best. It doesn't prove anything of the kind: it only proves that *you* think so, and that the beginner has confidence in your judgment. Other purchasers are those who are still increasing their requirements and need more supers than they now have. Such a one will say, "I want the best that's to be had. Mr. Root says it's the section-holder. He's so thoroughly reliable that I'll trust to him and get section-holders." Very likely he'll make an improvement, for he may be using something not nearly so good as section-holders; but if he has been using the T super, and finds on trial that he doesn't like the section-holder so well, it is not at all certain he will promptly make it known; and in any case, the fact still remains that he has increased the sale of section-holders without preferring them.

There are those—I have your own word for it—"there are those who have used the T super so long, and to the exclusion of all others, that they are not easily persuaded to use any thing else." Now, why? I suppose you include me in the number, and I suppose that I adopted the T super for the same reason others did—at least some others—because it was better than what I had been using. Would not the same reason make me change from T supers to section-holders that made me change from wide frames to T supers? I think I made a pretty fair trial of the two side by side, and, like the others who are stubbornly holding on to the T super, I did so because I believed it best.

Please remember this: The friends of the T super are not likely to say any thing about your preference. Take my own case. Personally, what difference does it make to me what you think about it? I have all the T supers I need; and if others buy section-holders, it's nothing to me. If you should try to rule out the kind of sections we prefer, then a howl would be raised because we should be stopped from getting what we wanted. But booming section-holders

doesn't touch in the same way, so nothing is said. But try to take away T supers, and then you'll hear something.

You will probably say I'm prejudiced. Why should I be? I've changed before; and unless I should die young I expect to change again. I am on the lookout for something better than the T super, and then I'll change to that. But it will hardly be the section-holder, for I have tried that and don't know of a single feature it has better than the T super. Can you name one? Now, instead of its being all prejudice that makes some stubbornly hold on to the T super, is it not possible there is some prejudice on *your* part? While giving you credit for none but the best of motives, I sincerely believe you are misleading those who look to you for guidance, and using your powerful influence in favor of an inferior article.

And now that I've made a good deal longer introduction than you did, I'll answer your question. Let us look at the points in the T tin proposed on page 215. Friend Anthony says,

 "The points 2, 2 wouldn't form cutting edges for hands and fingers, and would never become bent out of shape as much as the old kind do." I've no trouble with their bending out of shape with fair usage, and the duller edge would be had at the expense of nearly 50 per cent more tin; and, worse still, it would perceptibly raise the sections, making a larger space between top-bars and sections, and the bees would do a worse job of propolizing on this rounded edge than on the sharp edge of single thickness.

He thinks it would be a good thing to avoid "the rounding at the point 1" and have the sharp edge of the tin there. Well, my first T tins were all made that way, and I am still using them by the hundred. An objection to them is, that the sharp point 1 catches on the sections as you put them in the super, especially the last sections. There is much less trouble about the section catching on the rounded edge.

Now to come directly to your question, "Is a thickness of $\frac{1}{32}$ any worse than $\frac{1}{64}$?" Not a bit. It's just as easy, and a little easier, to close the larger space, for a thin piece hasn't as much stiffness to allow its being wedged in. You say, "If we could reduce it to nothing it would be desirable." No, it wouldn't, begging your pardon. Try once filling sections in a super where there is no play; and if you've quit swearing, there may be danger of a relapse. I want full $\frac{3}{8}$ of an inch play, then the three little top separators $\frac{1}{4}$ inch wide, and a shade less than $\frac{3}{8}$ thick, can be forced in and make a snug fit that would be utterly impossible with no play whatever. Whoever tries the two kinds of T tins side by side will, I think, prefer them as the Roots now make them.

Marengo, Ill.

[Your paraphrase of the quotation from my footnote does not quite give it as I would have said it if I had been enlarging upon it. T supers formerly had the lead; but they were not very well adapted to the Dovetailed hive, without making supers of different lengths from the regular hive-body. As the single-tier wide frame was very popular, and is now, and probably always will be, and as it seemed to have all the advantages of the T-super arrangement, and some peculiar to itself, we adopted it, but left off the top-bar. This omission, we find, had been begun by others before us. We give customers the option of the two kinds of super; but if they do not know what they want, we recommend the section-holder arrangement. We boomed the T-super arrangement in our 1895 catalog harder than ever, putting in a nice wood cut. But our packers hardly know what it is.

You ask me to give the names of those who have thrown aside T supers for section-holders. This I can not do. Why? I can best answer by making a quotation from your article above, wherein you say, "I do not expect to buy another T super as long as I live." The reason is, you have enough for your requirements, and you could not afford to throw them away for something perhaps slightly better. Now, then, if there are hundreds of other T-super men in the same fix, it is not likely they will discard their arrangement for the section-holder device; but we have had in times past a good many letters stating that they preferred the section-holders to the old T supers, but could not change for the reasons already given. I could not give you the names, because I was not then interested, and did not preserve them. The fact is, doctor, you have become accustomed to the T super (and it certainly is one of the very best arrangements), and your habits of working fit it better than any thing else. I have said before, there is a good deal in getting used to a thing. For instance, I know of some women who would not change their old cook-stoves, true and tried, for all the new-fangled stoves in the market. They have become accustomed to them, and know just how far they can go without burning their bread. They have become used to the swing of the doors, the position of the reservoir, the handling of the griddles, and yet nine judges out of ten would say their old stoves were very much inferior to the new ones. There, doctor, I do not mean to say you are an old fogey, and have become wedded to your old arrangement; but honestly now, doesn't the stove illustration *partly* fit your situation?—Ed.]

MORE QUEENS SAFELY TO AUSTRALIA.

I beg to announce the safe arrival of the two queens by September mail. I should have written you before, but I have been very busy. All the bees except the queen were dead in one cage; queen and all the bees alive in the other. Candy was in a good state of preservation. Bees commenced comb-building in the one all were alive in. My friend Edmunds informs me to-day that two out of three queens forwarded to him arrived all safe on the 16th of this month, so that you are much more successful this year than last, in so far as this district is concerned. I find your queens and progeny produce splendid honey-gatherers, besides being very gentle and prolific — all the advantages required by any bee-keeper. Your queens should command ready sale. It seems all that is required is safe mailing to Australia, when no doubt you would obtain many orders from Australian bee-keepers.

JNO. GARDNER.

Hurstville, Sydney, N. S. W., Oct. 27.

RAMBLE 131.

IN LAKE COUNTY.

By Rambler.

WHEN we rounded over the hill that looks down upon the little straggling town of Lower Lake we could see no signs, even, of a lake far or near. When we were putting our camp in order, an inebriated Dutchman came shambling along, and I asked him how far it was to the lake. He bland-

ly replied that it was 12 miles.

"There, Wilder," said I, "I told you there was no lake near us. How many rivers, creeks, and lakes we have crossed that have had no water in them!"

When we had our camp all set, and horses picketed out, we discovered we were in the next yard to a winery. That accounted for the drunkenness of the Dutchman. The poor fellow lost his hat and his bundle, and lay beside the fence as stiff as a poker for several hours. This was another object-lesson showing the beauties of wine-drinking.

Our next socially disposed visitor was an old resident of Lake Co., and in age he was an octogenarian, his silvery locks falling over his shoulders; his bent form and staff reminded one of an ancient prophet. He informed us that only an arm of the lake projected into that portion of the county, and it was only a mile and a half away. Our venerable visitor being an old resident, and having filled various offices of trust, he, in true California style, extolled the many good features of Lake Co. He said but little about its being the Switzerland of America; but he said, in a half-serious way in relation to the healthfulness of the country, that no one ever died in Lake Co. If they wished to shuffle off the mortal coil they would have to go over into Napa or Mendocino Counties. He gave us the average death-rate, and it was only 1 in 114, and this was not a very good day for death-rates either. He was thoroughly posted otherwise in relation to the statistics of the county, and informed us that there was plenty of room for settlement, as only a tenth of the land was occupied. The hills and mountains produce the best of fruits, while the valleys were adapted to grain and stock raising.

There were but few signs of apicultural pursuits, and the country so far had the appearance of scant honey-bee pasturage. We had observed, however, several familiar eastern honey-plants. Here was a patch of heartsease; then a sprinkling of sweet clover; here a fine

field of buckwheat, and mulleins. Their tall stalks and yellow blossoms transferred our thoughts in an instant to the old back pasture-lot in Eastern New York. Mr. Wilder inquired of our neighbor the fruit-rancher and winery-owner if there were any bee-keepers about.

"Yes," said he, "there's one just out at the other end of the town—Mr. Shires."

I resolved to spend at least a portion of the evening with him, and made tracks for his residence. I broke in upon him just as he was finishing his supper. Of course, having supplied the wants of the inner man, he was in a good humor, as all good men are upon such occasions. I found him a progressive bee-keeper, well acquainted with the reputation of A. I. Gleanings and the Rambler, and his greeting was cordial. Allow me to introduce Mr. Z. P. Shires. Mr. S. is not a very tall man, but he has much steam-engine about him. He is a married man, and has a swarm of seven children—four boys and three girls; and although he has so many strings to hold him down to one location and a steady occupation, he is quite a Rambler. He was born in Tennessee, had lived in Florida, Alabama, Texas, Washington, and California. Even now in this glorious Switzerland of America he showed some signs of discontent, and thought of moving to Upper Lake; and if that did not suit him he would go back to Alabama.

Mr. Shires is a very enthusiastic bee-keeper. He had been in his present location only eight months; but in that time he had cut down 60 bee-trees, all of them within two miles of town, and many in town. From the 60 colonies thus obtained he had saved 54, and had them nicely at work in Langstroth hives of his own construction. I visited him Aug. 26th. Since February, say a little over six months, he had cut the trees, transferred the bees, and, in addition to building the most of their own brood-combs, they had made a good amount of honey in 1-lb. sections, and his sales of the same had amounted to \$96. The bee-trees would sometimes yield a wash-tub full of honey. One colony occupied a cavity 6 inches in diameter and 14 feet in length. His bees were then, Aug. 26, at work upon honey-dew on the oak.

Mr. Shires described a remarkable feature of the country in the fact that, at certain seasons, honey-dew comes in veritable showers. The dew is seen to drop from the sky—not only seen, but felt on the clothing, and it covers all manner of vegetation with a sticky substance. The bees work upon it with great energy, and the quality of the honey is good.

There were but few bees kept in the Lower Lake region, and the persons who owned them had a mortal dread of the moth-miller. Mr. S. thought if they knew a little more about bees they could easily manage the pest. Foul brood is unknown here, and we hope it will continue so to be.

Like all of California, the spring months gave an abundance of flowers; but in June there is a short time of scarcity which sometimes endangers the life of the colony unless closely watched and fed.

At Upper Lake much alfalfa is grown, and Mr. Shires had an idea of moving to that locality, where he thought a greater amount and better quality of honey could be produced; but there is no better evidence needed to show the abundant honey-flow of this locality than the number of bee-trees.

In the morning Mr. Shires came over to our camp with a nice basket of fruit and some samples of his comb honey; and, how opportune! We had ceased to say, "May the shadow of Pryal never grow less." for the honey he gave us was all gone; and now we changed our opinion, and thought that the Shires shadow ought never to grow less; and how can it, with a swarm of seven children?

The objection to making a business of bee-keeping in this locality is its distance from railroad transportation. Mr. S. found sale for his honey in the home markets. We felt much benefited by meeting Mr. S., and were better posted in relation to honey-production in Lake Co. At the close of our fraternizing we turned our faces in our respective directions; and soon Lower Lake was a memory of the past.

Lake Co. is noted for its numerous mineral springs and health resorts; and, as a native said, the country seemed to make a good share of its living off the tourist. We desired to do our share toward supporting the country, and resolved to take a turn among a few of these resorts.

At Seigler's Springs we found a fine hotel, many cottages, and tents; but owing to the hard times there were but few occupants. The sparkling waters reminded me much of the mineral waters of Saratoga, N. Y. We lunched at Seiglers, and then pushed on toward Adams Springs; a rough, stony, and steep road tried the mettle of our ponies, but we accomplished the journey without accident. I was pleased to note in many places by the wayside quite thrifty little fields of sweet clover. The bees were working upon it quite freely, and they were presumably from the surrounding trees, for there were no bee-keepers in the vicinity.

At Adams Springs the mountains closed in to a narrow gorge. Here we found hotel and stables, and numerous cottages. There was barely room for a road, and we nearly despaired of finding a camping-place. We did, however, find a little square spot large enough for our tent, and we decorated the side of the mountain with our wagon, blocked with stones, and our ponies hung, as it were, to the bushes.

When we bade Mr. Pryal farewell in Oakland he partly promised to join us in Napa and enjoy with us for a season our travels and camp-life; but hearing no word from him we could only hope that he would follow on and overtake us.

We had been two weeks from Oakland, and his shadow had grown very dim, and here in this wooded country we had given up all hopes of his arrival.

MR. PRYAL'S UNSEASONABLE VISIT CREATES SOME ALARM IN CAMP.

We had retired, and were about to send up our somniferous orisons, when we heard a tramping of many feet up the narrow roadway—a lantern and a rough voice intimating that those hobo fellows had better get their tent out of that or they'd get pitched out. Our valiant Jack rushed out to the defense, and the parties halted. Mr. Wilder followed the dog to see what all the racket was about; and whom should he meet but our friend Pryal? It is needless to say that we gave this bee-keeper of Oakland a cordial greeting. He had been upon our trail for several days, and an extra push on the lines, and a late drive enabled him to overtake us. We gave him a soft corner of earth in our camp for his bed; here he rolled his blanket around him and soon forgot the toils of the day in sleep, with the rest of us.

MR. PRYAL AND HIS RIG SUSAN B. ANTHONY.

In the early morning we saw a sort of nondescript animal across the gulch, and Mr. Wilder was the first to exclaim, "Hello! Bro. Pryal, where in the name of the equine race did you get that hoss?"

"Eh? oh! That horse and cart is the property of the paper I represent—the *Pacific Rural Press*—best agricultural paper on the coast; only \$2.00 per year; circula—"

"But that boss," said I, "what's the pedigree? What's the name of the animal, anyway?"

"Well, gentlemen," said Mr. P., "she's a strong-minded animal, and her name is Susan B. Anthony. Her pedigree is from away back. She's the missing link between the donkey and the giraffe."

We all gathered around Susan B., and admired the various points of interest; and a snap shot will enable the more expert horseman to judge the ancient dame.

THE DIVISIBLE-BROOD-CHAMBER IDEA— WHOSE PROPERTY IS IT?

AN INTERESTING DISCUSSION ON PATENTS AND
PATENT DECISIONS.

As announced in our last issue, we give space to both Mr. Heddon and Mr. Danzenbaker to reply to statements on pages 267, 268. Neither one has seen galley-proofs of the articles in this number, and so both stand on an equal footing. I desire, above all things, to give both an equal and perfectly fair hearing. To let one reply to either one of the two articles in the present issue, and not the other, would be hardly fair; but as either one in a very large measure covers the points advanced by the other in this issue, it seems to me that further replies are unnecessary—at least in our columns; and I feel very sure that Mr. Heddon will grant space to Mr. Danzenbaker, if he so requests it, in his own paper, for the further discussion of the matter. As the latter's article came first we give it first. It is as follows:

Editor Gleanings:—I have neither time nor inclination for needless discussion, and I had hoped the world was wide enough for Mr. Heddon and the rest of us; but as he talks titles, laws, courts, and the sheriff, I desire the privilege of defending my position.

Mr. Heddon says: "My patent covers a divisible brood-chamber, used as and for the purposes specified in said patent." These purposes specified are the same as have been time and again written in bee-journals (by himself), in his circular and book; there is no mistaking it, and no getting around it. Dear reader, sometimes good men are honestly wrong. Two locomotives can not pass each other on a single track, and we can't both be right. The unsupported word of either of us can be weighed by all intelligent readers at their own estimate.

If friend Rambler, and others whom it may concern, will refer to the files of record in the U. S. Patent Office, showing the history of Mr. Heddon's case, they will find that he was not the first to invent and patent a multiple or divisible-brood-chamber hive, and has no legal or moral right to support his threats of prosecution, as he was informed at the time, when applying for his patent, in which he made a broad claim as follows: "7. In a bee-hive, a brood-chamber constructed of two or more horizontal, separable, and interchangeable sections." This clear-cut claim shows plainly his purpose; but it was rejected, with all of his ten claims except the 3d, by the Patent Office, as being *old and common rights*, and were dropped by his attorneys, and he

was restricted to *limited* and combined claims, as title-deeds are made subject to existing incumbrances. The Patent Office, by these limitations, expressly reserved what it had already granted to others. Mr. Heddon had to confine his claims to a construction of bottom-board, break-joint honey-board, and a case with thumbscrews through its sides, and cleats in the opposite corners, expressly limited, showing that the cases, cleats, frames, and screws, all old and common, were combined to effect his purpose, which defines and limits him to using these things as described, but does not prevent others from using any of them in other ways for the same purpose; and he is debarred from interfering with others using what the records of his own case show were denied him, and yielded absolutely by him at the time of his application. Numerous and recent decisions of the Supreme Court can be cited, showing the fallacy of Mr. Heddon's pretensions, as in the two cases below:

Sargent vs. Hall Safe and Lock Co.
114 U. S., Judge Blatchford.

"In patents, for combinations of mechanisms, limitations imposed by the inventor, especially such as were introduced into an application after it had been persistently rejected, must be strictly construed as *against* the inventor and *in favor* of the public, and looked upon as in the nature of disclaimers."

In case Keystone Bridge Co. vs. Phoenix Iron Co. 95 U. S., 279, S. C. said: "As patents are procured *ex parte*, the public is not bound by them; but the patentees are, and the latter can not show that their inventions are *broad* than the *terms* of their claims; or if broader, they must be held to have surrendered the surplus to the public."

What if Mr. Martin does say, "In making my frame close fitting, and also to the case, the combination is clearly an infringement upon the Heddon claim"? If Mr. Heddon had such claim (but the history of his case shows clearly and distinctly that it was denied him, *as old and a common right*), neither Mr. Heddon nor myself have been allowed to fence it off from the public, and we can not honestly claim it.

Mr. Heddon's objections to the sheet-metal lining and frame support have never been made by others who have seen my hive. This sheet metal does not warp, shrink, nor swell, and is covered over between the uprights and cases, insuring a uniform bee-space, with slack enough to press lightly against the uprights, and yielding enough to avoid jamming, if the frames swell. This end play is a decided advantage over the Heddon hive. They can not be glued to the case by the bees, and are easier to empty than a T super when full of either frames or sections. I first made and used it in place of the T supers, having never seen a Heddon hive until several months after I got my patent, although I had seen the drawings.

If Mr. Heddon's claim did cover the close fitting of the upright to the case, my hive would not interfere with that claim as they do not touch the case at all, but rest and bear against the metal support that hangs upon the case, and it can be used in other styles of hives. My claim is a broad one, without limitations, as I am at this date the first inventor of it. No set-screws are needed to secure the frames tight and solid in position, as they can now be carried bottom side up if need be, and they can be wedged up or set free with a plain gouge chisel, with half a turn of the wrist.

While apparently resembling the Heddon hive, mine does not use his style of frame or section. It is furnished with the exact style of top and bottom barred brood-frames and the prize sections, oblong in shape, used by Capt. J. E. Hetherington, of Cherry Valley, N. Y., which, after a careful test, I find the best in use, as 25 per cent. more of them will go on the same hive-space, and they sell for 5 to 10 per cent. more in market. Mr. Martin says such hives are well adapted to California, and he writes me that he likes my ten frames and sections better than the longer and shallower sections, irrespective of any claims as to infringements.

Mr. Heddon puts much stress on "the state of the art" to which an invention belongs at the time that invention was made must be considered in construing any claim for that invention." When he invokes this, let him *not forget* that nine of his ten claims were rejected *as old, and common rights*, and his patent is only a combination of cases, cleats, screws, frames, sections, *all old*. Where is the invention?

Functions! whatever that may be, it is too esthetic. You might as well try to patent a purpose or a principle which is as free as God's pure air and sunshine that he designs for all. Patents must define constructions or fixtures so clearly that one skilled in the art can make them. The venerable Langstroth may have been robbed of his just rights; but you, Mr. Heddon, are secure; it is impossible to rob you of what never belonged to you, either before or since the Patent Office rejected your claims, and you have accepted what you could get, like the rest of us.

There is no patent court of equity that was established in 1870, or any other time, different from other courts for patent-cases. Equity courts originated during the reign of Richard II., and come to us from our earliest history, your assertion to the contrary notwithstanding. If I am trespassing on your legal rights, I will gladly surrender; but as we can not think alike in this case, I will agree to abide by the decision of three reputable judges, each of us to choose one, they to select the third. Until you do this I declare publicly, as I well know, that my patent does not infringe any claim of yours, neither legally nor morally.

Mr. Heddon's reference to a bundle-carrier impales himself exactly. The other fellows had been there nearly a score of years ahead of him, which he knew then and now, as the records of the Patent Office in his own case clearly show that he mutely submitted at the time.

The limitations of Mr. Heddon's claims absolutely prevent him from interfering with others using what was denied him. He certainly can not claim more than his title calls for, any more than a squatter on a quarter-section could claim the State. As for management, his circulars show that he has revised it materially since he set out, and I prefer a very different one for myself.

Washington, D. C.

F. DANZENBAKER.

In order that the reader may more clearly understand just what Mr. Heddon's patent, dated Sept. 29, 1885, does or does not cover, we reproduce his five claims. They read:

1. In a bee-hive, a case consisting of a frame one of the sides of which is provided with thumb-screws extending through said side, and the opposite side of which is provided at the corners with narrow cleats facing said thumb-screws, substantially as and for the purpose set forth.

2. The combination of the bee-hive, the bottom stand having end pieces of less height than the side pieces, and the detachable bottom-board, the ends of which are provided with downwardly extending cleats resting upon the end pieces of the bottom stand, and the upper side and rear edges of which are provided with cleats adapted to support the lower case of the hive and afford admission-space for the bees, substantially as and for the purpose set forth.

3. In a honey-board for bee-hives, the combination, with a frame, of a number of slats secured to the bottom sides thereof at a bee-space distance apart, said frame being even with the bottoms of said slats and projecting a bee-space above them, substantially as and for the purpose set forth.

4. In a bee-hive of the described case, the combination, with the brood-chamber of a hive the tops of the frames of which are bee-space below the top edges of the hive and a case for surplus honey the bottoms of the frames of which are even with the bottoms of the case in which they are secured, said frames for surplus honey hanging parallel with and directly above the frames of the brood-chamber, of a honey-board consisting of slats secured to a frame, said frame being even with the bottoms of said slats and projecting a bee-space above them, substantially as and for the purpose set forth.

5. In a bee-hive, a brood-chamber consisting of a series of reversible and interchangeable cases, each of said cases being provided with thumb-screws extending through one side and with cleats at the corners of the other side and facing said thumb-screws, and of a number of reversible frames rigidly secured therein between said thumb-screws and cleats, and a stand and cover, substantially as and for the purpose set forth.

In testimony that I claim the foregoing as my own I have hereunto fixed my signature in the presence of two witnesses.

[I have since obtained copies of patents No. 33,668, 196,060, 203,890, that are said by the attorney Mr. Danzenbaker to antedate Mr. Heddon's claims of the divisible-brood-chamber hive. We can scarcely afford to give room to the whole of the patents in question, but we make extracts touching upon the points at issue, so far as they concern the novelty of a horizontally divided brood-chamber. Patent 196,060, bearing date Oct. 8, 1877, by J. C. Train, makes the following claims:]

1. In a sectional bee-hive, the combination, with each of the sections thereof, of two or more fixed partitions, G, and a corresponding number of comb-supports, H, removably secured to the fixed partitions, substantially as described.

2. In a sectional bee-hive, the combination, with the lower section having grooves or mortises formed in its lower side edge, of a hinged bottom, substantially as set forth.

3. In a sectional bee-hive, the sections formed with two upper edges provided with tenons and two with rabbets, the inner edges e of which are cut away to afford bearings for the comb-supports G and H, while the lower edges are formed with two mortised edges and two rabbeted edges, in combination with such supports, substantially as set forth.

[Two paragraphs in the descriptive matter also read as follows:]

My invention relates to an improvement in bee-hives, the object being to provide a bee-hive of such construction that it may readily be adjusted in size to meet the wants of either large or small colonies of bees, and the several sections removably secured together in a water-tight manner, to exclude moisture and dampness from the interior of the hive; also, to provide space in the lower portion of the hive wherein the mother may collect and be removed therefrom without disturbing the bees.

It is evident that any number of sections may be employed, and a complete hive secured to the apiarian at all times, as, in case the honey is to be removed from the upper section only, the upper section may be removed entire, if desired, and, the cover or top J being replaced, as all the sections are made to accurately fit each other, a complete and water-tight hive is thus secured.

[Patent 36,668, dated Nov. 5, 1861, by H. R. Terry, contains these paragraphs in descriptive matter:]

My improvement consists in constructing the hive in horizontal sections, fitted to a suitable base and provided with a top, which forms a roof or cover, each section being separated from the others by series of slats, and connected together when in use by hooks or other equivalent fastenings, which admit of the ready detachment and removal of any one of them. The sections are three or four inches in depth, which permits the formation of combs, which are suspended from the upper series of slats. Each section is provided with a glass light F, covered with a slide, to admit of the inspection of the bees while at work. The sections being readily removable, any one of them may, when filled with new honey, be changed for an empty section thus taking the place of honey-boxes, and any number may be added to increase the capacity of the hive and adapt it to the size of the swarm. By this means the troublesome method of transferring the bees from a smaller to a larger hive, and vice versa, is entirely dispensed with and much time and labor saved.

[Patent 203,890, under date of May 21, 1878, shows a series of shallow cases containing regular frames over the brood-nest. The only claim under this patent is for a brood-chamber having concave or arched sides.

Patent No. 2592, dated April 29, 1842, shows a series of shallow chambers fastened together with bolts. They were simply shallow boxes, I judge, without brood-frames or any thing of the sort. There is no printed descriptive matter.

Patent No. 2929, dated Jan. 27, 1843, by J. Harris, contains a similar series of horizontally divided hive-sections, one piled upon another. These, like the one just preceding, contained no brood-frames, as a matter of course.

If any one is interested in following these up further, he can secure them by applying to the Commissioner of Patents, Washington, D. C., giving the number and dates as above given. It will be necessary to inclose 15 cts. for each patent called for. Stamps are not accepted.

Possibly our readers would like to have me enter an opinion (inasmuch as I have studied the patent question to some extent) as to whether the patents above cited would cover the divisible-brood-chamber idea specified in Mr. Heddon's patent. Such a statement as I should feel like making, I am sure, would please neither party; and I therefore prefer, for this and other reasons, to take no sides at all, as I take it that our readers are intelligent enough to decide the merits of the case after comparing the claims of Mr. Heddon's patent with those above cited, and reading his article.

As Mr. Heddon seems to be pretty well acquainted with the patents above given, the references that he makes to them, and his reply thereto, will probably cover what he desires to say concerning them in the article that now follows:]

REPLY TO ATTORNEY WILLIAMSON.

Infringement, or desire to infringe, are, either or both, prima-facie evidence of utility.—WALKER.

Bro. Root:—I have this day discovered Mr. Danzenbaker's attorney Williamson's attempted defense of his client's infringing hive (not patent), in your Trade Notes in April 1st GLEANINGS. While I regret that you should have printed such a communication, and also that two weeks should elapse before the sophistry could be shown up, I am pleased at your editorial remark that "both sides shall have a fair and impartial hearing."

Mr. Williamson is in the position of a paid attorney, and we all know what that means. It is no reflection upon the gentleman's character, to infer that he deems it a moral duty to carry the point desired by his client, right or wrong. Now, Mr. Williamson is discussing a subject before an audience of bee-keepers, not one in fifty of whom have sufficient knowledge of the same not to be misled. The members of this audience have been compelled to devote their time and intelligence to other matters; but these other matters have cultivated their inherent logic; consequently, it is more in this line than strictly in the line of patent law that I shall reply to the learned attorney. My own knowledge of patent law enables me to answer definitely and successfully every point raised by Mr. W.; and, in fact, my article preceding it, and the paragraphs from Walker's Patent Law, found in my 1890 circular, do most completely answer every point that he brings up; and these I commend to those of your readers who may understand patent law as well as or better than I do myself; but this article I shall confine principally to the illogical position of Mr. Danzenbaker and his attorney, believing it will be the better understood by our just and logical bee-keepers.

Allow me to call the reader's attention to the fact that Mr. Williamson makes no mention of patent law in equity. He speaks of my natural or "moral rights" as though he had seen a proof of my foregoing article. If Mr. Williamson is given room for another article, I request you to mail me proof at once, when I will have my Washington attorney append a reply to the same, which will unquestionably end all discussion on the legal aspect of my right to my earnings as an apicultural inventor. No one knows the state of the art so well as bee-keepers; such students of our literature as Prof. Cook, Hutchinson, Clark, Mason (and, without taking further space, twenty other prominent bee-keepers), would never have proclaimed "new, original, unexcelled, a revolution," etc., were I now the owner of nothing of any value. If such could be true, of what use is our patent office? and of what service are our patent-solicitors? Such would be an everlasting stain upon Mr. Williamson's profession. My attorneys will undoubtedly be as anxious to defend the title to my property, a document of their creation, as Mr. Williamson is anxious to tear it down, as a paid attorney in the interest of Mr. Danzenbaker. They will undoubtedly be able to defend the right, especially as "possession is nine points in law." The misleading arguments of Mr. Williamson, made for the purpose of dispossessing me of my earnings, by claiming that there is a flaw in my title to the same, are an exact repetition of the Langstroth history; of the attack upon the natural rights of the man we have subsequently sainted as the bee-keepers' greatest benefactor. If it were true, that any of the features of the Danzenbaker hive, which belong to Mr. D. (claimed in his patent), were of any value, Mr. Williamson's line of argument would as completely rob Mr. Danzenbaker, could it be successfully carried out in the practice of bee-keepers, as it is intended to rob me.

I call your readers' attention to mistakes, both in statements and deductions, in Mr. Williamson's article, as follows: He says the two hives are similar in construction, *only* in the matter of divisible brood-chambers and top covers. That is not true. If Mr. W. knew aught of the state of our art, he never would have mentioned "top covers," and, further, would have known that the close-fitting frames, at the same time closely fitting the case, prior with me, was the second essential feature of my hive, and imitated by Mr. Danzenbaker. He asks if my patent contains any claim which by a "fair construction" can be held to be infringed by the D. hive. "Fair construction!" Here Mr. W. admits that patent courts take into consideration the matter of "fairness" in construing the breadth of a patent-claim, and by this bee-keepers may know

just where our suit at law will come out at the end of a damage-suit against Mr. Danzenbaker's customers. Of course, Mr. Williamson must say something, because he is paid for so doing. The above shows clearly that Mr. W.'s statement, that claim five of my patent is the only one that touches upon the features of construction common to the two hives, is a gross error.

Next, Mr. W. quotes a claim of my original application which was rejected by the patent office, but fails to inform your readers that it is wholly covered by the last eight words of claim five, which read: "substantially as, and for the purposes set forth." In answer to another misleading statement of Mr. D.'s attorney, let me explain that I never claimed to be the prior inventor of every kind of brood-chamber which could be divided "for the purpose of increasing or diminishing its capacity." I so stated in the discussion which arose relative to the Ekes and Nadirs of France and Germany. My claim is on a divisible brood-chamber containing frames; one capable of the manipulations of modern apiculture, for the purposes set forth in my specifications. What are these purposes? Not only to "contract or enlarge" the brood-chamber, but to alternate its upper and lower parts, to produce certain results in the surplus sections of the hive. Now let me quote to you from the great authority, Walker:

"Novelty of a thing is not negated by any other thing fundamentally incapable of the functions of the first."

"Novelty and patentability are not negated by the fact that every part of the thing is old."

"Novelty of any thing is not negated by another thing which was not designed or used to perform the functions of the first."

The above is a complete answer to Mr. W.'s misleading quibble regarding the revision of my claims, made to suit the Patent Office, and still holds as much as before.

Now, Bro. Root, you say that you have sent for the three copies of old patents my attorney was cited to, as referred to by Mr. Williamson. Why, bless your soul, 22 citations were handed out by the examiners, and yet only three or four of them contained a single feature in any way resembling any part of my hive, and these were nothing fatal to the value of my patent. Firing at us irrelevant citations is a privilege of the examiners. These 22 copies I lost in the fire in Patent-Attorney R. B. Wheeler's office in Detroit, about four years ago. I have never replaced them, because they have no bearing against the title to my property, when rightly understood. I will ask one question, which, if bee-keepers can not answer in the affirmative, the argument based upon these citations falls to the ground. Are you willing to, and do you expect to use, the features and functions shown in these old patents, *as and for the purposes therein specified*? If not, what do you propose to do? What is it that is just now so greatly desired? Fill GLEANINGS from cover to cover with nothing but sophistical, misleading, and confusing discussions by patent-lawyers, and, in the end, down in the hearts of all honest bee-keepers will remain this verdict: "To Heddon belongs the practical, divisible brood-chamber, with its reversible cases and close-fitting frames closely fitting the case, as and for the purposes specified in his patent, and further explained in his book, Success in Bee Culture."

To close, I will say that I notice your statement, that you "take no side in the matter." I believe you should, and believe you will—not with persons, but with principles. I know that you know the property to be mine, all the time you are discussing the question of the technically legal title to the same; and I think it strange that, in your last issue, you confuse yourself wholly to the matter of title, utterly ignoring the question of right *per se*. It seems to me that this is almost the only point the mass of your readers can understandingly decide upon, and upon that I know they are already decided. However, if you wish to educate us all in the details of patent law I will not be displeased, and my attorneys will be on hand promptly.

It seems to me that the matter stands about like this: Mr. Martin has voiced the sentiments of nearly all of our bee-keepers in proclaiming the fact that Mr. Danzenbaker's hive is a "gross infringement" on my invention. No one has ever claimed that I have infringed any man's rights. Nine years elapsed before any such claims as attorney Williamson's were made, because it required that length of time for Mr. Danzenbaker to discover the value of my invention. Why does not Mr. D. apply his patent-

claims to a hive-construction which does not infringe mine? (Remember that it is his *construction* and not his claims of invention that infringes.) I thank you for your offer to give us all a fair and impartial hearing.

JAMES HEDDON.

Dowagiac, Mich.

[Mr. Heddon indirectly asks whether a proof of his former article was sent to Mr. Danzenbaker's attorney. No such proof was sent; but I wrote to Mr. D., requesting that his attorney state whether Mr. H. had either a legal or a moral right to the divisible-brood-chamber idea, and hence Mr. Williamson's reference to the "moral right."

Whatever legal claims Mr. Heddon may or may not have, if he has, by these years of advertising, made popular a certain system—if he has been the first one to show the *world at large* that it may have points of merit, then he certainly has a kind of moral right—a right which I think bee-keepers will be quick to respect. Understand, I do not go so far as to say that he has or has not legal or moral right to certain hive-constructions. I could render an opinion, but, as I said, I shall adhere strictly to the ground of taking no sides. I can not do any better than to repeat the words of the great Master of all things, who said, under similar circumstances, "Render unto Caesar the things that are Caesar's." Naturally, after the severe way in which Mr. Heddon has criticised us in the Dowagiac *Times* extra, we should be inclined to take sides against him, but this should and does have nothing to do with the matter at all. I do not very often stand "on the fence;" but for the present, at least, I do not know of any reason why any of us here at the Home of the Honey-bees should desire to get on either side of said fence.—Ed.]

A NEW DEPARTURE.

"Trade Notes," a corner in which we poor inventors may blow our horns "with none to molest or make us afraid," as I see from the last issue of GLEANINGS. Now, that is "fair play," and we all like fair play—at least, for ourselves; we are not always so particular about the other fellow, I am afraid; so I will just trot out my hobby—a kind of hobby it is, the Crane smoker, which is henceforth to wear that little motto, "*Patented March 12, 1895*," which witnesses that the United States government, through one of its departments, has carefully examined into my claims, and has pronounced them "new and useful," and that it is ready, through its courts, and, for aught I know, its army and ironclads, to defend them. My claims are very quickly told: An air-chamber situated between the fire-chamber and bellows, one end extending and opening into base of the fire-chamber, and the other communicating with the outside atmosphere, and a valve so situated as to open and close alternately this opening, so that, as the bellows closes, the valve opens, thus forming a continuous passage from the bellows to the fire-chamber; and when the bellows opens, the valve closes, thus giving a draft to the fire-chamber.

The advantages to be obtained are twofold—a strong blast, and the exclusion of smoke and sparks from the bellows; and when the smoker

is properly constructed I believe these advantages are fully attained.

So far as I know, the use of a jacket of tin completely surrounding and extending some way below the fire-chamber toward the bellows is original with me. I think it would be better if plain tin were used for this purpose, and small washers were used where it is riveted to the fire-chamber, so it would set out $\frac{1}{2}$ inch from it on the back, although it might not look quite so well then as now manufactured.

My claims were allowed some months ago; but for various reasons I delayed having it issued until the present month.

There are some obvious reasons why a new invention, or an improvement on an old one, should be patented, one or two of which I will mention: It greatly facilitates its introduction to the industrial world, and often enables the manufacturer to pay the inventor a fair royalty, and then, by manufacturing in large quantities, be able to sell them for even less to the consumers than would be possible if a large number of persons engaged in their manufacture without paying royalty.

J. E. CRANE.

Middlebury, Vt., March 22.

NON-SWARMING BEES.

Question.—Three years ago last June I purchased a queen of you said to be reared by the plan given in your book. This queen has done well for me; but the point of interest just now is this: Although she has kept her hive full to overflowing with bees, fully as well as any queen I have, yet only one swarm has issued from her colony since I got her. About the time I received her I purchased your book and reared a few queens in accord therewith. Very few of the queens so reared have led out swarms, and the bees behave very similarly to those from the queen purchased from you, while my other colonies have kept up excessive swarming each year. The queens not reared in accord with your book were reared under the swarming impulse, by colonies casting swarms, as are the most of the queens in any apiary where the bees are allowed to swarm. Now, I should like to know if you claim that queens reared by the plan given in "Scientific Queen-rearing" have a greater tendency not to swarm than those reared by the bees during the swarming season, as most bee-keepers allow their bees to rear them.

Answer.—I have never made the claim that queens reared in upper stories, over a queen-excluder, while the reigning queen was doing good work below, were less inclined to swarm than were those reared when the bees were pre-

paring to swarm, as I formerly raised all queens, then claiming, as many do now, that queens reared under the swarming impulse were the very best possible to raise. Some twenty years ago I noticed that queens reared to supersede a failing queen were less inclined to swarm than were those reared during the height of swarming, and so noted the matter on my diary; and during all the time intervening, since I first noted this matter, I have had no cause to change my first conclusion. Queens reared as given in my book are brought to perfection in very much the same way as are those reared when a case of supersedure happens; and I have noted that I have had less swarming in my apiary during the past eight years, through which time I have reared nearly all my queens over queen-excluders, than I formerly had; yet I would not think it best to put forth the idea that a continuation of thus rearing queens for a quarter of a century or longer would give a race of non-swarming bees. When God told all animated nature to go forth, "multiply, and replenish the earth," he implanted in the same a nature so to do; and if that nature is not carried out in bee-life, through the issuing of swarms, it will come about through the intervention of men, by way of such manipulation of hives as will throw the colony out of its normal condition, rather than by breeding for a race of non-swarming queens. At least, such is my opinion. I have received many letters similar to the above, relative to less swarming occurring since the parties writing had practiced the plan of raising queens as given in "Scientific Queen-rearing;" but it must be remembered that the past few seasons, taking the country as a whole, have been rather poor seasons, hence would be conducive to less swarming. Of course, there is no harm in watching this matter; but to put forth the claim that a persistent rearing of queens over a queen-excluding honey-board will bring forth a race of non-swarming bees would only end in disgusting those who went into such a trial with a full belief in the honesty of the one making such claim.

COLONIES LEAVING THEIR HIVES.

Question.—What is the cause of bees leaving their hives with clean honey, clean hives, and quite a quantity of brood, in the spring of the year? Three of my colonies have deserted their hives in this way on warm days; and although I have put them back they will not stay. What can I do to remedy this matter?

Answer.—This is a case of what is termed "swarming out" by some, and "spring desertion" by others. In an experience of a quarter of a century I have had about a dozen such cases, and in each one it has happened after a hard winter, such as the past has been, and with colonies which had wintered imperfectly. Some think it is caused by the bees becoming discouraged, and abandoning further effort to

keep up the temperature of the hive so as to keep the brood from perishing. In nearly every case which has come under my notice, colonies deserting their hive have become reduced as to numbers to a greater or less extent by spring dwindling; while the number of bees, compared with the amount of brood, was ill proportioned, considering the outside temperature. I used to think that such swarming out could be accounted for on the ground of lack of stores, moldy combs, etc., as has been told us many times in the different bee-papers of the past; but after having several swarm out when all was clean and nice, the same as is spoken of by our questioner, I had to give that up and conclude that those who had told us that such was the cause were mistaken. Some seem to think that the chief cause of this swarming-out mania lies in excitement on the part of the queen, the same happening at a time when few young bees are in the hive to keep company with the queen, when a general flight of the bees takes place, which often happens during the first warm days in early spring. During such occasions the queen becomes excited about being left with so few bees with her, goes to the entrance, takes wing, and sallies out to join the circling bees; and when once in the air with the bees the whole alight as a swarm. But I can hardly accept this as the cause, for the reason that, as our correspondent states, when we hive them back again in their own hive, they will swarm out again and continue to swarm out till they enter some other colony or go off entirely. As to a remedy, I doubt whether there is any better than to unite such with some other colony, although I have tried giving a frame of hatching brood from some strong colony to them, removing all their brood and giving it to the strong colony from which the frame of hatching brood was taken. Next, place this frame of hatching brood together with one frame of honey next one side of their hive, and confine the bees to these two frames by means of a division-board till they become strong enough to take more frames, when they are built up to full colonies. This is the plan I used to adopt with good results, where for from any cause I desired to save just that individual colony. Lately, since the queen-excluding zinc has become common I have simply hived back in its own hive the colony swarming out, and placed a strip of perforated zinc at the entrance, thus keeping the queen from going out, in which case the bees will return after each swarming-out; and if such colony so treated does not die by dwindling it can usually be saved in this way. But, as I said, unless for some reason you wish to preserve the individuality of any colony which once swarms out, the best thing to do is to unite it with some other colony, as the work required to make a good colony of such a discouraged colony amounts to more than any ordinary colony is worth.

Heads of Grain

FROM DIFFERENT FIELDS

THE RECORD BROKEN AGAIN ON DEER-SHOOTING BY A BEE-KEEPER.

On page 170 Mr. J. D. Given asks for a better record on shooting and killing game than he has. I will admit his score is good, and hard to equal. I used to think I was fairly good with the gun myself. I use a rifle instead of a shotgun. I have stood in one place and killed five deer with six shots. The gun was a single-shot breech-loader. The first shot I fired, the deer was about forty feet distant, and the last one was about 400 feet. There were only five deer in the band, all full grown black-tails. I have frequently killed three and four out of a band before they would get away. At another time there were four of us boys worked up to a band of elk. I killed three while the other boys got none. At another time there was a party of ten of us went on a buffalo-hunt. We killed 42 buffalo, 6 antelope, and 2 deer. I killed 39 of the buffalo, the 6 antelope, and 2 deer. I have fired 26 cartridges without missing a single shot, and with the same I killed not less than 10 tons of meat. Seeing this is not a sporting-paper I will let up; but we have bee-keepers here who have records all right. This shooting was done from 1868 to 1876. Use this if you see fit; and if you wish any more records I have plenty left, on up to killing Indians.

BUCKSKIN CHARLEY.

Aurora, Neb., Mar. 13.

[Among his other accomplishments "Buckskin Charley" is the inventor of a section-press and foundation-fastener that seems to have merit, judging from the engravings and description in a circular sent. Verily, is there any thing bee-keepers can't do between being legislators and breaking the records on shooting deer? By the way, I am interested in gunning. When I was sick last fall, and convalescing, the doctor prescribed the shot-gun and long tramps. I got both of them, but *game*—not any. Indeed, I "broke the record for the county" in missing every thing I shot at. May be if we had deer here I could miss them too.—Ed.]

SCORE FOR THE BEES.

At the Oregon Experiment Station, peaches were grown under glass, and forced, by artificial heat, out of their natural season. In such culture, it is necessary to pollinize the flowers by some artificial means—a brush or otherwise. This is very slow, tedious work. Bulletin 34 of this station tells what was done: "To save labor in transferring the pollen, some trees were sprayed when in full bloom with warm, others with cold water. This proved very unsatisfactory, more fruit dropping at the stoning period than in the case of trees pollinized with the brush. As a further experiment, a hive of bees was placed in the house when the trees commenced to bloom. This was in November,

and a heavy fog prevailed for 15 days; and although the flowers were constantly opening, not a bee showed itself. During the night of the 15th the fog lifted, and the next morning was bright and clear, causing the pollen to burst. Then the bees came from the hive and kept up their work for eight or nine days. The result was, that not a single peach was observed to drop at the stoning season. So great was the amount of fruit on the trees, that it was necessary to thin it. One tree in the house was securely protected, so that bees could not gain access to it, and all of the fruit dropped at the stoning period."—*Rural New-Yorker*.

THAT EUROPEAN AUTOMATIC SMOKER.

Mr. Chas. Norman, in "European Matters," talks about an automatic smoker. I inclose an

illustration. I don't think it will ever do for any "go-ahead" bee-keeper. Some one of my acquaintance having seen it says the automatic movement, produced by a kind of clockwork, is very noisy. My impression is against this smoker. You can judge for yourself.

Winter has been very severe in France; but our situation behind the Alps, in Nice, has kept away the fierce cold all our neighbors had to undergo this exceptional year. We had snow three times, though not to stay longer than a day or two. In Palestine my people want rain, especially in Jerusalem—very much exposed to east winds, which dry up every plant. Last year, 1894, was a very poor season here. I hope 1895 will be better. I didn't have one-fifth of my usual honey-harvest.

Nice, France. PH. J. BALDENSPERGER.

[The smoker is not reproduced because I think it practicable for this or any other country, but because it represents an idea.—Ed.]

HONEY FROM RASPBERRIES.

I wish to attempt to correct two mistakes in your list of seeds of honey-plants, which I cut out and inclose. I was brought up on a fruit-farm, and have kept bees since I was 12 years old. It is the *red* raspberries that the bees work on principally. They work some on black raspberries, and a very little on blackberries; but the bulk of the raspberry honey comes from the *wild* red raspberry. The cultivated is as good, or better, but there is not enough of it.

Sanct Run, Md.

C. A. MONTAGUE.

CORRECTION.

Friend Root:—In GLEANINGS for March 15, you apparently committed me to the proposition that bee-paralysis is hereditary, by your

headline to my paper on that subject. It should have been headed "Bee-paralysis Contagious." I do not believe that the disease is hereditary in the strict sense of the term, but that an infected queen will communicate the disease in the ordinary way by contact. I do not wish to reopen the discussion of this matter, but simply to make a correction. T. S. FORD.

Columbia, Miss., April 9.

THE GOSPEL OF ART.

Work thou for pleasure; paint or sing or carve
The things thou lovest, though the body starve.
Who works for glory, misses oft the goal;
Who works for money, coins his very soul.
Work for work's sake, then, and it may be
That these things shall be added unto thee.

KENYON COX.

H. Y., Wash.—Bees can not, with any satisfactory results, be kept in a room adjoining the kitchen over winter. You had better leave them outdoors. In your climate they will probably winter all right. It might be advisable to put over them winter protecting-cases.

W. S. Y., Ia.—We leave chaff cushions on the hives along toward the first of June in our locality. It is better to leave them on a little too long than not long enough; in fact, it does no harm to leave them on all summer, only that they take the place of section-crates or any supers designed to take surplus.

W. B. R., Va.—The braula, or bee-louse, we sometimes find on the backs of imported queens direct from Italy; but we never knew them to make any serious trouble. The bees themselves will soon remove them when the queen is introduced into a strong colony. We do not know where you will find any further particulars than those given by Prof. Cook in his book.

H. M. S., O.—We would say we recommend the use of full sheets of foundation in the brood-frames; medium brood if wired, and heavy brood if unwired. Yes, we recommend wiring, running the wires parallel with the top-bar. Yes, use thick top-bars.—Carniolan queens are preferred by some; would refer you to John Andrews, Patten's Mills, N. Y., or Mrs. Jennie Atchley, Beeville, Tex.

M. J. A., R. I.—Hives, as a general rule, should face the east. If they are placed toward the south it gives them too much sun in the middle of the day. If they face the west they are apt to get too much wind; if toward the north, also too much wind and too much cold. Taking all things into consideration, having

hives point toward the east is preferred by the majority of bee-keepers.

W. F. C., Ore.—When the bees build the combs crosswise we don't know of any way but to cut the combs out, straighten them out, and fit them back into the frames by the directions that are usually given for transferring. If they are too crooked for that, use the Heddon short way, given on page 32 of our catalog. We always advise beginners, and everybody else, in fact, to put at least a small starter in each brood-frame; otherwise they may have a condition of things much like yours.

W. H. W., Tex.—The half-inch space in the Dovetailed hive, back of the division-board, has a purpose. If every thing fit down in the hive snug and tight you would have difficulty in removing the Hoffman frames. We therefore have provided what we call the "lateral play." Remove the brood-frames; shove the division-board into the half-inch space. That breaks propolis connections. Remove the division-board, and then you have room to shove over the brood-frames and handle the same easily.

J. M., Kan.—A good deal will depend upon locality as to whether you can use two-story eight-frame hives with the section-crate on top. The colony should be a tremendously strong one, with brood and honey in both stories before any surplus will be put into the sections.—Bees will be likely to fill the second story with honey or brood before they occupy the section-crate.—The yield of section honey from the two eight-frame bodies all depends upon your locality, season, and size of colony.

J. R. W., Minn.—The circumstance you relate regarding drones from black queens is not an unusual one. Indeed, the progeny from hybrids—that is, a black queen fertilized by an Italian drone—will vary all the way from black to bright-yellow bees or drones. We very often see some very nicely marked Italian drones from queens that are perfectly black; therefore it is not color always that decides purity. If you were to take some of those nicely marked drones, and mate them with pure Italian queens, if it were possible, you would find the resulting progeny only $\frac{1}{4}$ Italian.

G. F. H., Cal.—The best inside lining for a solar wax-extractor of small size is Russia iron. Zinc and galvanized iron would darken the wax, and, besides, would reflect back too much of the light. Of course, if you can get an asphaltum that will not be affected by the heat or the wax it will make no difference what metal you use. The asphaltum used by photostock dealers for painting developing-trays would be about the thing. For large-sized extractors there is nothing better than matched boards of butternut wood, or something that will not shrink much. These, of course, should be painted black.

EXTRA pages and extra editions as usual. It is a good time to advertise and to send in new names. Yes, indeed, the new names are coming in fast now, so our subscription clerks reports.

BRIGHT sunshine, the merry hum of the bees, good bicycle roads, piles of orders, lots of work, and a good spring all around, are making us here at the Home of the Honey-bees happy. Our buildings were never filled with so many employees as now.

W. O. VICTOR, of Wharton, Texas, one of the prominent and leading bee-keepers of that State, sent us a couple of twigs from the rattan vine. It yields considerable honey in that State. He says it usually yields first-class honey anywhere from ten to twenty days.

In our occasional department, headed "Question-Box," I have concluded not to state the question, because it is usually implied in the answer. I do this in order to save space. The answers that are published are a few selected from our daily correspondence, that I think are of general interest to A B C scholars.

It is a pleasure to announce that our friend and co-worker, Mr. R. F. Holtermann, of the *Canadian Bee Journal*, has received from the Ontario government the appointment of Lecturer on Apiculture at the Ontario Agricultural College. He is also in charge of the experiment apiary connected with the college. He is a good man for the place, and we shall look for some good work.

WE have received but one call for Given foundation made on rolls. Either it is or is not a good thing; and I am anxious to see it tried by different bee-keepers, not so much for the paltry profit there may be in fussing with a small quantity, but to determine whether it has real merit in the hands of others. We are ready to put in one, two, or half a dozen sheets with your regular foundation, when so requested.

From the last *American Bee Journal* it appears that the usual \$500 appropriation for the benefit of the Illinois State Bee-keepers' Association will not be granted this year. "The dairymen fared the same as the bee-keepers, and the horticulturists are not sure of getting any thing much better," writes Secretary Stone. The cause is attributed to the condition of the State treasury.

WE have now obtained some lysol, that new drug for curing foul brood, mentioned by C. J.

H. Gravenhorst as giving very satisfactory results in Germany. See his article on page 308, last issue. We will, till the supply is exhausted, send out a small vial of the liquid, a sufficient quantity for curing several colonies (10 cts.), to those who may have foul brood in their apiaries, and who care to make a trial test and report. It will be folly for American bee-keepers to shut their eyes against all drug remedies, and claim that there is no cure but extermination and the foundation plan.

WHATEVER legal or moral claims Mr. Heddon may really have over the Danzenbaker hive, it is but just to Mr. Danzenbaker to say that, so far as I know him, he would not appropriate any thing that properly belongs to another, not even an idea. He thoroughly believes, and I think he is honest in that belief, that his hive is not an infringement, and that Mr. Heddon does not have either moral or legal claim over any feature of the Danzenbaker hive.

HOW FATHER LANGSTROTH IS APPRECIATED BY A BEE-KEEPER IN COSTA RICA.

A PROMINENT bee-keeper, who does not wish to have his name printed, but living in Costa Rica, the most southerly of the small republics constituting Central America, seeing the article on page 170, March 1st GLEANINGS, soliciting funds for Mr. Langstroth, very generously sent a contribution of \$10.00, asking us to forward the same to Mr. L., whom he considered a real benefactor to him also. The amount was forwarded, and has been acknowledged with thanks by Mr. Langstroth's daughter.

I am sure our American bee-keepers appreciate this, not because of the largeness of the gift, but because of the spirit which prompted it. I can only regret that many of our American bee-keepers, using the Langstroth system, have forgotten to send in their annuity fund even when they agreed voluntarily to send it each year as long as Mr. Langstroth lived. I am informed that our venerable and much-respected friend is in very feeble health, and he does not seem to improve with the charming spring weather. Any funds that may be sent in will be received by ourselves, or by Geo. W. York, 56 Fifth Ave., Chicago.

DEATH OF CHRISTOPHER GRIMM.

As we go to press, a notice reaches us that Christopher Grimm is no more. Most of our readers knew him as the brother of Adam Grimm, and one who has for many years made it almost a religious duty to be present at the meetings of the North American Bee-keepers' Association. In fact, we well remember his genial smile and hearty handshake at our last meeting at St. Joseph. Christopher Grimm was known all over the United States as the successful and intelligent bee-keeper, his number of colonies reaching at one time 1000 or more.

I remember him as one of the brightest types of a genial, good-natured representative of Germany—a man of the most strict integrity and honesty. He was born at Halenbrunn, Germany, March 18, 1828, and died April 20, 1895. His home for the last thirty years has been at Jefferson, Wis. A. I. R.

STATISTICAL REPORT ON WINTERING.

In response to our inquiry in our last issue, for reports on wintering, we have received about 100 letters. I was surprised at the good showing. Scarcely one had lost over 33 per cent, and there was a very large number who had lost absolutely none whatever. As was to be expected, inexperienced and slipshod bee-keepers did not winter as well as those who read bee-journals. But before these reports came in, quite a number of our agents who are selling our goods wrote that they would not be needing the usual amount of bee-supplies, as bee-keepers had lost pretty heavily all around them. I have wondered whether they, the agents, were not guessing that the losses would be much greater than they really were. The fact of the matter is, that, although we have had very severe winter, the spring and fall were unusually favorable; and experience has shown, time and again, that it is much harder to "spring" bees than to winter them. After a severe winter and a moderate spring, bees will come out from their winter quarters in very much better condition than when the reverse is true—a moderate winter with a prolonged cold spring.

HAS "HE DONE AND GONE AND DONE IT?"

"OBSERVER," in *Progressive Bee-keeper* for April 1, gives expression to the following:

We knew Ernest Root was incubating something to take us in with some time ago, and now he's "done and gone and done it." That twelve-frame hive is what's the matter now. Say, friend R., can't you give us a rest? We don't want any more new hives for a while yet. What we want is more honey, and more money for the honey. Will the twelve-frames give us that?

If I have advocated the twelve-frame hive in preference to the eight or ten, I did not know it. I believe the most I have ever said in its favor was that there was a possibility that large hives would give better results. I knew our sixteen-frame colonies at our basswood yard last summer had done better than the eight-frame; but this was only one straw. A short time ago, from the testimony that came in I concluded, and so expressed myself on these pages, that sixteen was too large, and that, if we must have large hives, the twelve-frame was the extreme limit. The substance of this opinion is given in several different numbers, and I do not see how from this I have "gone and done it" or how I was "incubating something" to take in the unsuspecting. I have written the hive matter in our catalog; and

while admitting that ten and twelve frames may be preferred by a few, I urged strongly the use of the eight frame—see second paragraph, page 4. Dear me! Some one else has been saying that I am an advocate of a double brood-nest. I did not know it before. I am simply open to conviction, and have been *trying* to call forth the truth, no matter whether it favors supply-dealers or anybody else. If we *ever* adopt the twelve-frame as the standard it will be much against our will and our pocketbooks, as well as the pocketbooks of bee-keepers who might be foolish enough to follow every such fad. Take it all in all, Observer, if I am not very much in error we stand on about the same footing, and I therefore indorse your two last sentences heartily; but at the same time do we want to shut our eyes to the value that there may be in other systems and in other managements? It is a publisher's business to dish up the truth impartially. Am I not right?

WHAT I THINK ABOUT PATENTS.

WHAT do you think I have on my desk, in a prominent position? A patent-binder—not something that I patented myself, but a binder containing copies of patents of all important apicultural inventions. We have made arrangements whereby we now receive a copy of all patents on apicultural inventions as soon as they are issued from the Patent Office. Some of them, I feel sure, will never bring their owners any return; others give promise of being useful, and perhaps will be of some advantage to their owners in a pecuniary way. I hope so. Whatever may have been the opinions of my respected parent in the past, the more I look into the patent system in the United States the more I feel like admiring it. Although it has its defects, the system in our country, I believe the world acknowledges, is the most perfect in the world. And the fact that some of the greatest and most useful inventions have emanated from this land is evidence along this line.

Are we going to patent any of our recent devices? No—that is, we have no intention of doing so now. But I have advised one or two—yes, several—to secure their ideas by patent, even when I knew that such a patent might compel us in time to pay royalty. As examples of this I would refer to the Crane smoker and the Porter bee-escape, both now well-known and useful implements. I believe most thoroughly in the idea that inventive genius, and the product of the brain in this line, should be rewarded. On the other hand, I believe that our patent system should be so modified as to restrict some of the fearful abuses connected with some of these patent-monopolies. I am glad to see that the Supreme Court has recently made some much-needed and substantial limitations.

ON THE INDIAN RIVER.

The Indian River is generally mentioned as a synonym of something balmy and tropical. On the morning of the 7th of February, however, there was a keen northwest wind, and things were not so very tropical after all. Friend Gifford is employed by the government to light and trim the lights that are kept constantly burning for beacon-signals along the Indian River; and you know Uncle Sam's business must be attended to, visitors or no visitors. Friend Gifford had been planning to take me on this trip; but I was pretty nearly sick, and the state of the weather seemed to indicate that the trip would have to be given up. But I changed my mind before he reached the boat-landing and followed after him. Up in the garret of the Gifford home there was a heavy old overcoat that had done service away back in Vermont. After having had about ten years of repose in said garret it was brought down on that eventful morning. It was large enough so I could get it on over my own overcoat, and, thus rigged, I began to take almost my first lessons in running a sail-boat under a heavy wind. I enjoyed the trip, however, very much, in spite of the wind and cold. These beacon-lights are to direct the boating craft after dark; and as it is necessary to go several miles to replenish the lamps, they are allowed to burn night and day, the expense of the oil being less than the cost of travel needed to keep them lighted all the time. One not accustomed to boating might think a steamer could go anywhere. Not so, however. The highways of vessels are laid out almost like the roads overland; and wherever there are dangerous points, piles are driven at stated periods, projecting above the water enough so a board may be nailed on, indicating to the pilot of the boat the channel. Sometimes these guiding-posts are within a quarter of a mile of each other or even less; again, they are a mile or even two miles apart, the pilot understanding the signification so that he may avoid the shallows. Well, in the night time they use these lamps as a guide to the pilot, and they are near enough together so that one or more of them are always in sight. At each lighting-station our little sail-boat had to be securely lashed to the framework of timbers supporting the light. Then friend Gifford climbed aloft with his substantial copper lamps, carrying a great hood made of sail cloth, to cover himself and lamp while he did the trimming and filling, and cleaned the chimneys, etc. It seemed as if the wind would tear the boat loose sometimes; and, in fact, unless very stout ropes are used, boats often do break away. When the wind was the highest, it was necessary to lower the sail before trying up the boat; and then it had to be hoisted again when we started out amid the boisterous wind. Sometimes it seemed as if we surely would upset. But friend Gifford had a knack of handling the flapping sail as an expert would handle a vicious colt. Just once the rope got caught, and I thought we were going over sure into the cold briny water, amid the boisterous and almost deafening gusts of wind. But he was equal to the occasion; and once when the water actually came over into the boat a little, and I began to turn white from the scare, a single glance at his self-possessed smiling countenance reassured me. I shall long remember that experience on the water;

and I enjoyed it greatly, although I did get cold and stiff before we finished our day's work. He said it was almost the first unpleasant day for the work he had had for the business in all the years he had held the post.

The next day, although it was still cold, we started out to see the bee-keepers. We stopped briefly at the home of Mrs. J. D. H. Weir, Toledo; but the weather was so cold that both the bees and the interesting family of children were kept pretty well indoors. Children seemed to be so scarce in that part of Florida that it rejoiced my heart to get a glimpse of even a tolerable-sized family. If we don't have any children we surely can not have any schools; and if we do not have schools, what will become of us?

We made a brief call at Woodley, and then pushed on to friend King's, where I reluctantly decided I was too sick to go any further. I have mentioned briefly something of that pleasant visit prolonged to several days when I expected to stay only an hour or two. Friend King is a very quiet, still sort of man; but even if he does not talk much he does a tremendous lot of thinking; and, by the way, a big lot of work comes about in his quiet sort of way. Several times I heard him nailing up work before daylight; and when I was up so as to look out of the window, there he was out in the dooryard, working by the light of his lantern. He has now several hundred colonies of bees, and has secured some crops of honey almost equal to those a little further north around New Smyrna. His good wife busies herself with a fine flock of poultry numbering almost a hundred laying hens, while he looks after the bees and makes the hives.

FLORIDA ANTS, ETC.

In many parts of Florida they are pestered by a species of large ant. At Daytona I found some of the bee-keepers setting their hives on legs, and planting each leg in a dish of water. But even then leaves blew in on top of the water and made a bridge for the ants to get over. Besides, unless the water was watched it would evaporate from the dishes, and then the ants would get through again. Friend King studied over this matter, and finally went to the woods (all about him), where pine-trees are so plentiful and cheap, and cut down some tall trees. Two of these were placed side by side, and spiked together just far enough apart to hold a hive conveniently; then legs were put on to this long frame so as to raise it up to a convenient height for working. Then the legs of this huge bench were set in wooden troughs hewed out from these same pine logs. You see, when the wooden trough is filled with water it lasts a good while; and three of these troughs will hold a frame long enough to support, say, a dozen or may be twenty hives of bees, the long frame being supported at each end and once in the middle. After he had got his apiary of several hundred colonies fixed in this way he decided it would be cheaper to cut a ditch clear around his apiary, house, and garden, and then fill the ditch with water. The ditch is needed any way, where there are so many forest-trees, to prevent the roots from the forest coming in and using up his expensive fertilizers. After the ditch was finished, however, he found that the water was not actually needed. The soil is so sandy that, when the ants get to the bottom of the ditch, they find it impossible to climb up the steep sides, because the sand gives way, especially if the ground is dry, and lets them roll back into the ditch. After he got the ditch all finished he said the ants came from the woods in great bodies, and literally piled up beside it, and stayed there days, evidently mad because they could not get over to the hives and help themselves to the

honey and young larvæ as they had done in former days.

By the way, friend King is a pretty determined man when he sets out to succeed. He found the ants did most of their brooding in rotten logs in the woods, so he took his wife's flock of poultry, coaxed them out into the woods with corn or other grain, then chopped open the logs and taught them to devour the white larvæ of the ants. The chickens soon became very fond of such food, and in time he came out victor. The ants got along very well with the water-troughs and even the ditch; but when he retaliated by taking his hens out into the woods to eat the ants' larvæ—their children—instead of letting them eat the young bees from his hives, they concluded, evidently, that this was a little *too* much. It was the last straw that broke the back of the camel, you remember; so the ants packed up their tents and moved away to a healthier locality. And, by the way, there is a lesson or two right here. When we begin to wage a determined warfare on any insect-foe—so determined as to take up the *aggressive* instead of the defensive, and follow them to their *holes* as it were—they will pretty soon take the hint and abandon the ranch. Tracking and chasing them up to their breeding-places is, a great many times, cheaper than drugs—Terry's plan of managing potatoes, for instance.

BEE-PARALYSIS IN FLORIDA.

Friend King has had some experience with bee-paralysis, and he tried an experiment that was new to me. He took some of the brood from a suffering colony, and put it with a healthy colony to see whether the bees, when they hatched out, would have the paralysis. Has anybody else ever tried this? Is the disease one of the brood, or is it something that the bees get after they are able to fly? If I remember correctly, he said they had no paralysis in the new hive on a new location. This does not strengthen my position that I took so many years ago; namely, that the diseased bees were those reared from a certain queen, and that, when you remove the queen and put in a healthy one, the disease is cured.

On this Florida soil, where fertilizers must be used, at least on the greater part of it, I found there is much discussion and much uncertainty, as with us up north. Friend King paid \$22.00 for a ton of what he called Gainesville fertilizer, and he says he does not believe it did him a nickel's worth of good. Very likely it was something his soil did not need. His poultry manure, however, always gives a sure and profitable return; and he says he verily believes the manure from the poultry is worth half as much as it costs to feed them, even when fed on grain that has to be shipped down from the North. In other places I found similar statements. Poultry manure always tells on almost all kinds of garden stuff or fruit. One of Mr. King's neighbors saved half an acre of melons during the freeze by covering them with sand. He is an unmarried man, and went out to see his "best girl" on that eventful night. When he returned home to his ranch at half-past eleven at night he realized the danger his melons were in. You know melons are planted a good way apart, and therefore it does not cost so much to cover each hill with sand. He worked about three hours, and all were saved except a few where he did not put on quite enough sand. Friend King saved 1500 tomato-plants through the first freeze, by a similar proceeding; but he lost them all during the second. Some of them had tomatoes on at the time, as big as hickorynuts. When I was able to get around, my friends declared I must stay at least one more day to visit

PELICAN ISLAND.

It was not *altogether* curiosity that made me want to see this wonderful island. As the water all about the island was quite shallow, we were obliged to use a row-boat; and even this ran aground so many times that we were some time in finding a landing, and succeeded only by wading (Mr. King *carrying* his better half) ashore. Before we reached the island a swarm of these strange birds, with their queer-looking pouch or gripsack hanging to the under side of the bill met our view. They are as large as a good-sized goose, or perhaps a little larger; and we found them not only filling the air but on the water all around the island; and on the island itself were hundreds and thousands, apparently sitting still with their funny-looking heads sticking straight up, and that long queer bill, with its appendage, hanging almost straight down. They did not seem to be very much afraid of us, for we could come up near enough to hit them with clubs were we viciously disposed. Hundreds of nests met our view containing eggs, young just hatched, and from that up to birds of all sizes until some of them were ready to fly. The freeze had driven the fish away into deep water, and the poor things were having a sort of famine on account of the unusual cold. In fact, the young pelicans were suffering to such an extent that, when we came along, they would open their mouths and beg most piteously for their accustomed food. They even hopped out of their nests, and ran after us with mouth stretched wide. The scene was so touching and painful that I turned away. The friends assured me that nothing could be done but to wait for warmer weather and the reappearance of fish. This island has probably been the breeding-place of these birds for ages. In fact, the manure has accumulated to the depth of several feet, covering the island, and almost extinguishing vegetation of every sort. At one time it was suggested that this sea-bird manure might be of value like guano; but the trouble is here, the fertilizer is not only drenched by the incessant rains of Florida, but at stated periods the salt water is blown by winds almost over the entire island. One wonders why these birds should come from miles in every direction to congregate on this one particular bit of land. The island contains perhaps some four or five acres; and it is almost completely monopolized by the birds. If these birds have been in the habit of roosting and nesting here since they came on the face of the earth, why should not this deposit be still larger? I believe friend King told me that the oldest inhabitants have a sort of tradition that there *was* a time when the island was not thus occupied. If this be true, what should cause the birds to change from one place to another? I afterward discussed the matter with the State Chemist, of Lake City. He also agreed that the accumulation of fertilizer was of little or no value. The guano of commerce all comes from islands where little or no rain falls, or from caves where birds and bats congregate, protected from the rain and its consequent leaching.

The second thing that interested me in regard to this island was the fact that here, right under my eyes, was a poultry establishment carried on entirely without the guiding hand of man. The birds themselves, and the instinct implanted in them by the great God above, managed the whole thing and did it successfully. Now, if pelicans can breed and multiply enormously without human agency, why can not a properly arranged island or inclosure be made to do the same with common fowls? If we have not breeds adapted to the circumstance demanded, then get somebody to

furnish us the breed. I once had one little brown leghorn hen that I verily believe would have peopled a farm with poultry all alone by herself, and in a very short time too, if plenty of food could have been provided for her and the chicks.

"Are pelicans' eggs edible?" you may ask. I think my friends told me they were eaten by some people; but as the diet of the birds is exclusively salt-water fish, the eggs are rather rank in flavor. Now, if any reader of GLEANINGS can tell me of a successful effort at raising poultry where they manage to raise chickens all by themselves, I should like to hear about it. I suppose you know the enormous wealth of the great cattle-kings of California, Arizona, and Florida, is secured in something this way. The cattle run wild, and breed after nature's fashion, the hand of man never coming in at all except to put the proper brand on the calves as fast as they arrive at a proper age. The flock grows and multiplies as the years pass, without any management from the owner—the only condition being, indeed, a sufficiency of pasturage.

On our way home we stopped at a pretty little point called Orchid; and it was quite an agreeable surprise to find, away out in the wilderness, a pretty little home full of books, magazines, and periodicals, presided over by a newly married couple—Mr. and Mrs. Forester. In their beautiful garden, watered by an ever-flowing artesian well, we found orange-trees containing leaves, blossoms, and fruit in limited quantity, unharmed by either the first or second freeze. This little bit of Eden is protected by both water and the great tall spreading palm-trees. It is on a strip of land between Indian River and the ocean-beach. We also saw beans under the protection of the palm-trees, that had passed the ordeal of both frosts. This would not have been sufficient, however, were it not for the water on each side of it. The place has been named "Orchid" because tropical plants like the orchid here find a safe place to grow and thrive ordinarily. The plan of irrigation here is to have the artesian-well pipe come up in the center of the garden, say four or five feet above the general level; then, to avoid the expense of more iron pipe for conductors, the sand is banked up nearly to the top of the pipe; and in the top of this ridge of sand a little ditch is made with a gradual incline. This takes the water off in different directions across the garden; and with sand ridges to hold the water it is conducted between the furrows where they want it. Of course, much water is wasted by leaching through the sandy loam; but the artesian well gives such an unlimited supply from a four-inch pipe that it can waste all it wants to. Of course, when the garden shall have increased so that it becomes an object to utilize all the water, iron pipes will probably take the place of the ditches on top of the sand ridges. After having had such a visit as I did with friend King and his wife, and with Mr. and Mrs. Forester, it makes one feel like thanking God that there are such real nice people in this world of ours.

The wind was still boisterous when we undertook to climb from the landing down into the little row-boat. I was so much of an invalid after my recent sickness that I did not attempt to help very much. In fact, I was so unused to such treacherous things as boats that I needed help most of the time myself. Mr. King had charge of the management of the boat, and his wife was obliged to climb down and secure a foothold while the boat was swaying to and fro. She came near falling at one time; but instead of grasping for the secure timbers of the pier, she held tenaciously to her

little purse, or satchel, forgetting she could toss it into the boat and use both hands to steady herself. Friend Forester here broke in with:

"Look here, Mrs. King, I want you to tell us what is inside of that precious porte-monnaie that makes you cling to it so frantically, as if it were of more moment than life and death."

Without waiting for her to answer, her husband replied:

"Why, she has not any *thing* in the pocket-book except a five-cent piece. That is just the way with women-folks."

I here came to Mrs. King's rescue by remarking that I had known quite a few *men* during my time who would hang to a nickel, even though they knew it would carry them down to perdition and death, but that I was sure it was the first time in all my experience where a *woman* risked her life by holding fast to the root of all evil, and that I for one strongly resented the imputation that womankind are given to such penuriousness. Mrs. King did not vouchsafe to open that precious pocket-book and tell us what it *did* contain; but we laughed long and heartily, especially as she did *not* go over into the briny deep. Then somebody sang out that a school of porpoises was rounding the point.

Is it lawful for a man to put away his wife?—MARK 10:2.

There are unfortunate and unhappy marriages in this world of ours, as we all know; and a good many times it would seem as if the two had better separate—that is, it would seem so to *human* judgment and wisdom, especially when we attempt to use that judgment and wisdom without asking for grace from on high to guide us. I am not sure but I have, under certain very extreme circumstances, myself advised the separation of man and wife. If I did, however, I am pretty sure that my conscience troubled me about it afterward. There may be a terribly bad state of affairs where they undertake to live together; but the older I grow, the more I am convinced that it does not mend matters to seek a divorce through the courts of law. In the first place, the *precedent* is a bad one. The example is bad for the community. It is *terribly* bad for the children. It seems to wrench things asunder—things sacred and holy; and wreck and ruin often follow in a way no one could have expected. Satan's stamp and Satan's seal seem to have been left on divorces of almost every sort. Sometimes I am consulted in such matters when told that parties can not live together. My reply has been invariably—that is, before I knew the circumstances—that they would find it more trouble *still* to undertake to live separate. Now, the story I have commenced to tell you, perhaps, does not bear me out in this. If we knew all the circumstances connected with it, perhaps it would, after all.

I presume most of you are familiar with our Savior's command in regard to this whole matter. In fact, it has been read and considered again and again. This much seems to be clear: Christ Jesus gave very little encouragement, and I believe mentioned only one case in which divorce might be considered excusable; and if I am right he at least advised that man and wife who separated on that account should not marry again.

When these two parties, John and Mary, were well along in life, a circumstance occurred that perhaps helped to hasten the separation. In the town where they lived, the editor of the village paper was getting to be very intemperate. He was not only squandering all of his own means, but he had commenced, also, to waste the little property that belonged to his wife before they were married. The wife, in despair, appealed to our friend John. His connection with the bank gave him an opportunity of knowing more or less in regard to legal matters, and he was, perhaps, a very good man, under the circumstances, to advise the poor woman. Out of the best of motives he also undertook to see if something could not be done for the intemperate editor. The result was a sort of joint stock company of three—John being one, the editor one, and the editor's wife the third. In this way an intemperate man was prevented from using up his wife's property; and finally he was so far reformed that the paper began to grow, and the printing-office did a thriving business, proving a profitable investment for all three. Under the circumstances, the wife's gratitude was unbounded to John for saving not only her property, but her husband from a drunkard's grave. Before John undertook this he consulted with his wife, and had her discuss the matter fully with the editor's wife. Mary declared she was quite willing, under the circumstances, that John should enter into this praiseworthy undertaking.

Let me digress a little right here to say that such arrangements are more or less risky and dangerous. Even though John had been at the time a devout Christian, which he was not, and even though this editor's wife had been one of the very noblest and best of women, which I have reason to believe she *was*, I think we should be exceedingly careful indeed how we undertake any thing that invades domestic relations to the extent of the case mentioned above.

The poor woman, when she saw her property was saved, and her husband too, which was of a thousand times more moment, felt, as I have just said, unbounded gratitude to John. My friends, Satan is not slow to take advantage of such a state of affairs; and it seems a little strange sometimes for us to be obliged to confess that there is but a single step (often a very short step) from the noblest and best instincts of humanity down to the lowest and most deplorable. The man who had been saved from his intemperate habits did not *stay* saved. He was not saved through Christ Jesus. I do not mean to discourage friendly efforts like the one above; but the man who breaks away from any terrible sin needs *more* than human agency.

One night John remarked he would have to go to the bank and finish some urgent business. His wife objected, but he said it had to be done. When he arrived home rather late, his wife had already retired. She asked him if he had been at the bank at work. He was a little surprised at the question, but answered, and, I believe, honestly, that he had. She charged him with falsehood, and finally admitted she followed him when he left home, and saw that he did *not* go to the bank. Then he remembered that, before going to his work, he stopped in for a little chat with a particular friend. She followed him, and saw them through the window. She probably was jealous of the editor's wife at the time; and even though she did not discover that he was anywhere near the woman, she *did* discover, or, at least, claimed she did, that he was untruthful; and if he was untruthful in one thing, why shouldn't he be in another? This is a poor sort of reasoning, as all will admit; but when a woman once loses

faith in her husband she is ready for all sorts of foolish suggestions from the green-eyed monster. John declared he *had* been at his work, and she declared again he had *not*. Was not this a foolish thing to dispute about? I wonder if it occurs to you, dear friends, just now, that *you* at times have been perhaps just as inconsistent and unreasonable as were these two. They were both wrong and wicked. John was tired, and wanted to go to sleep. They had got a going, however; and the poor wife, like other daughters of Eve, could not rest without the last word—and, in fact, I fear there were several "last words." John told her again and again that she must stop and let him have his sleep or he could not get through with necessary duties that were to be performed early in the morning; and finally when she would not stop he left the room and sought a bed in another apartment. I do not know whether he got the needed rest in the other apartment or not. I can thank God, and do thank God almost every day, that I can go to sleep quickly and readily under almost all sorts of circumstances; but I am quite sure I should never have found any rest or recuperation in that other room. The only possible rest for me would have been after I had kneeled down by the bedside, my wife kneeling with me, and asked God to forgive two of his children for being bad and wicked, and to help them to do better. I think I may safely say that, before the little brief prayer would be finished, my wife's hand would be in mine, and *then* we *two* could go to sleep. 'You may say,' perhaps, I need to thank God for giving me such a wife. I quite agree with you, for I have and do often; but, my dear brother, something seems to tell me that there are very few women in this world of ours who would not go at least half way toward a reconciliation and a settlement of disputes of this sort.

But these two friends of whom I am speaking were not Christians. Certainly neither one of them was in a Christian frame of mind that night. John continued to occupy another room from that time on. Friends began to notice the trouble; and Henry, whom I mentioned in the outset of the story (who was also by this time married), came over and plead with John. He asked John to forget and forgive, and to try once more. John replied that he had forgotten and forgiven so many times that the thought of it sickened him. He did not want to try any more; but for Henry's sake he finally yielded. It turned out as the intemperate editor turned out. Without God's grace and God's blessing the same conditions produce the same results again and again. "Ye must be born again," the Savior said, and there does not seem to be any other way but the new birth through Christ Jesus.

dreary months passed for these two. Mary finally said she was going home to her father's. John agreed, and suggested that she had better stay there for all time to come. Preliminaries were arranged as to who should have the children, etc., and then she bade adieu to her husband and the children she was to leave with him.

In a very few days, however, it was whispered that the editor's wife was the cause of the separation. She heard of it, and implored John to bring his wife back again, and offered to go with him. By this time the editor was back to his old habits worse than ever, and the poor wife was sinking into an untimely grave from abuse and neglect and privation. The shock and excitement of the scandal made it almost necessary that Mary should go back, to save a life. John sent for his wife to come back. The editor, however, had got some ink-

ling of matters through his befogged intellect, and about this time woke up enough to get down on the street just drunk enough to boast before everybody that John had sent for his wife to come back because *he* had pointed a loaded pistol at his head and told him to do so. John became stubborn and ugly, and declared he would never live with the woman again, even if she came back, and telegraphed her not to come. He told me he had been so harrassed and worn out from want of peace and rest that he was about ready to commit suicide rather than to undertake to live under the same roof with that woman again. You see, Satan had got matters well in hand by this time. When he gets a man, or woman either, where they say they would rather commit suicide than to do some other thing, he is pretty nearly master. If you want to know how many suicides come about in something this way, read the daily papers. Sometimes it is divorce, desertion, and suicide *too*. Years after these events John became a Christian. He and I went over the ground together. I suggested to him what a Christian would have done under the circumstances, and we pretty nearly agreed on the matter.

Now, friends, if in this little story I have seemed to blame Mary, or if I have unconsciously told how provoking and ugly a *woman* can be if she has a mind to, I have made a mistake. If, however, I have succeeded in telling you how provoking and ugly *both* men and women can be—even husbands and wives, and fathers and mothers, when Satan is allowed to get a foothold in the family circle, then my story has performed its mission. The inmates of any home are to be *pitted* when Satan gets the upper hand. They are to be pitied exactly as if the smallpox had broken out in that house and could not be stopped. If there were no remedy, and no help for Satan's work, then indeed would this world be a sad place to live in. But, dear friends, there is a remedy and a *cure* for all troubles of this kind—even Christ Jesus who came from heaven to earth to cast out Satan. If the dear Savior is not invited into your home—if he is not one of you—be assured Satan will come, and he comes *without* invitation. Yes, even *now* he is going about as a roaring lion, and we should be helpless indeed against his wiles were it not for the Lamb of God that taketh away the sin of the world.

GARDENING UP TO MAY 1.

When I got home from Florida I think I told you our crimson clover was all right. So it was; but the severe freezing and thawing, day after day, through the latter part of March and fore part of April, has, I fear, used it up. When I saw it so green and well rooted in March, I thought it was surely safe; but now there is scarcely a root of it left, and it is much the same with our White Multiplier and American Pearl onions. This time, however, instead of putting them on the creek-bottom, where I have for years past, we put them up on the swamp in the black muck; but the muck seems to be so loose that the roots could not get hold enough. Perhaps half of our White Multiplier onions are all right, and these that stood the freezing and thawing the best are on a well-underdrained clay soil. They look pretty sick even now as I write; but as the freezing seems to be over, I think they will fetch up. I

am going to try crimson clover again, and put it in earlier. But I tell you it is a relief to take a look at the lathyrus silvestris. Why, the way that pea-looking plant sends its roots down into the ground is just wonderful. Not a single weak plant has been disturbed in the least; and yet they stood in a very exposed situation without any sort of protection. They were on our rich plant-beds, however, where the ground was spaded down a foot or more. A single tap root goes straight down. Now, if this forage is relished by stock, what a wonderful thing it will be to have such immense quantities of feed year after year, without any care or attention except to keep cutting your fodder when it is big enough! Our sacaline-plants are taking hold and growing tremendously. I do not think I ever saw a plant have more vigor—no, not even a *dock*; but it does not look to me as if it were going to be as valuable for feed as the lathyrus. The latter, you know, is one of the plants that take nitrogen from the air. By the way, we have a relative of the man who introduced the lathyrus, here in our own country—Mr. Carl Wagner, of Economy, Pa. He advertises the *genuine* lathyrus, and says there are imitations. We have purchased 500 to test beside our own. His directions for cultivating are printed in English and German. Here is the English translation that came with our plants:

TO CULTIVATE THE GROWTH OF WOOD CHICKLING VETCH, LATHYRUS SILVESTRIIS WAGNERI.

This seed is to be sown during the month of April in a well-cultivated growing garden, in rows, and placed about 12 inches apart. The bottom ground must be well dug up and turned over, and the upper crust properly manured. Should this not be the case, an artificial fertilizer may be used, so that the outgrown lathyrus seed is penetrated by the mineral gases, etc., and the many roots forced through the sand, stone, or other rough bottom containing mineral strength. In such cases the seed is not always successful in taking root, and is mostly drawn by the aid of old or mother roots during the first season. A growing garden, continuously well dug up to a sufficient depth, may serve as a propagation-bed for at least ten years, without remission.

From the middle of October to the end of April of the next year, provided the ground was not frozen, these one-year plants may be transplanted in all directions, about 12 to 14 inches apart. The bottom of the field must be dug up and well turned over, as the nutriment will then last 20 to 25 years; whereas by ordinary plowing or turning over it may not do so well. The roots of the transplanted seeds are cut smooth, and supported to a height of 8 or 10 inches, so that, when the next row is dug, the ground covers the one just passed. These seedlings thrive best when the head is imbedded about two inches in the ground. If not set in deep enough, and the heads with the neck of the roots are exposed, the seedlings perish. Wet grounds or soft soil containing stagnant water will kill, where dry, deep, sandy stone soil is successful. It is not meant to reject good soil, but it should be dry. See item on chickling vetch in the New York Staatszeitung, Feb. 11, 1893; June 10, July 15, Sept. 2, and Sept. 30.

Economy, Pa.

STRAWBERRIES UNDER GLASS.

My strawberries under glass did not succeed during the past winter as they did the winter before. When the terrible freezing weather came on while I was in Florida, it was necessary to let on so much steam to keep our dwelling warm, the strawberries were pretty well cooked; but if they attempted to ventilate, the plants were cooked at the roots and scorched on their tops. If a little greenhouse were built right over the underground passage for exhaust steam, instead of the simple hot-bed with sash, it would equalize the heat, and make it possible to raise plants.

COLD-FRAME ONION-PLANTS.

This last winter we made a larger experiment

in wintering onions under glass than ever before. Only two varieties were tested—the Prize-taker and American Pearl. The seed was sown quite thickly in the beds in September. By the time freezing weather came on we had onion-plants with bulbs about the size of the end of your finger. The sashes were put on and moved very little through the winter. To prevent the beds from becoming too hot when the sun shone out, every third or fourth sash was made of glass slats such as I have described. Besides, the dogs walked over the glass, here and there smashing out a light. I told the boys to let these occasional lights be for ventilation, even if it did kill the plants right under the opening. These onions are so hardy that a very little protection suffices; and when the severe freezing occurred in March and April, with warm sunshine in the middle of the day, the glass saved these from injury. We usually tilted the sashes, however, in the middle of the day. These onions are now, April 24, some of them, nearly as large as hens' eggs. They will make nice-looking bulbs away in advance of onions raised in any other way; and the ground was made so rich with manure that we can let them grow so close together that they almost push each other out of the ground. This sort of treatment will certainly pay, for you can almost set your own price on beautiful nice onions away ahead of anybody else. Very likely the White Multipliers would work nicely under this treatment. I presume that, in a few days, we shall have trouble by many of the large onions sending up seed-stalks, because they made part of their growth last season. To obviate this we can pull out the seed-stalk, or pull out such onions, and sell them in bunches. Of course, these cold-frame onions would be a splendid thing for onion-plants; and I think it would pay to give twice as much for them as for onion-plants raised in the greenhouse, from seed sown in February or March. To produce plants, they should be sown a great deal thicker than we have them. Another season, I think I shall use a great part of our sashes in producing cold-frame onion-plants for early market. In fact, ever since the trade has started in onion-plants we have had orders for them before they were ready; but the cold-frame would *always* be ready. In our locality, and with our average freezing weather which we have in March and April, I should say the cheapest and best way to raise spinach is in beds just such as I have described for onion-plants. No heat at all is needed for either onions or spinach, if you plant them so that they get a good start in the fall, before the sashes are put on. The spinach is ever so much nicer than any we ever get wintered in the open ground. All your sashes can be easily utilized at a season of the year when they are hardly needed for any thing else. Late frosts are making trouble with our large twice-transplanted tomato-plants. We have put them in a bed having the sides so high that the sash is quite a distance above the soil; but every night, when it looks like frost, the glass lies on top of the tomatoes, crushing down their leaves and blossoms. This does not do any particular harm unless it is cold enough to freeze through the glass. But they are growing so now that they probably would not stand it very much longer.

We are still getting 15 cts. per lb. for lettuce, or 20 cts. where it is sold in five-cent packages. Our first pie-plant brings 5 cts. a bunch, three bunches weighing a pound. Our first asparagus brings 5 cts. a bunch, eight bunches to the pound. Of course, these bunches are very small; but we aim to put all our vegetables up in five-cent bunches. As the season advances

we make the bunches heavier. For instance, the first onions raised in the greenhouse are put up in bunches of 4 oz. each. As the season advances we give three bunches to the pound, then two, and finally a bunch weighing a whole pound, for a nickle. But in order to induce people to purchase more we sell 3 five-cent bunches of any thing for 10 cts. Of course, it is some trouble to do the bunching up; but our boys use cheap rubber bands, and it greatly facilitates the work of the man on the wagon. He simply says to his customers, "Five cents for a bunch of any thing, or three bunches for a dime." In this way there is no weighing up, no discussion, no bantering. Of course, each customer is to take each bunch as it comes. He is not to pull them over nor sort out the best. But in putting them up, the boys endeavor to have the bunches average of equal value.

I wonder how many of the friends are enjoying working with plant-beds and sashes, as described in the latter part of the tomato-book. Oh! by the way, I got hold of a new item in this matter during my Florida trip. You will notice in my travels how much I said of the protection furnished to garden-stuff by planting under trees. Now, with the plant-beds I have described you do not need to fear the roots of trees robbing your plants—that is, if you have some trees in your garden that produce a valuable crop. Let the trees help themselves. Bring in your manure, and bring in water; and be sure there is enough to go round. Apple-trees trained high, so the limbs would not hit your head, would be just the thing, and in the fall of the year the foliage will protect your tomatoes from frost so that you may have several gatherings after the frost has destroyed those, where there is protection from the trees overhead. The shade of the trees is really a good thing for many kinds of plants and crops during the extreme heat of the summer. And then just think how pleasant for the wife and children to "make garden" in the shade under large leafy trees. But in this business of *high-pressure* gardening the shade-trees ought to be something that bears crops of great value. The mango-tree, of Florida, where the fruit from a single tree brought \$150, that would be just the thing. Very likely grapevines could be trained high enough to give the right amount of shade, and not interfere with the work. You see, there would be no leaves at all until hot weather comes. In fact, I have seen magnificent crops of grapes grown on vines trained overhead, so one could just reach the clusters. Of course, there are crops that need all of the sun; but there are a good many that do better without *all* of it. We have raised beautiful cabbage, celery, and tomato plants, where they were shaded a great part of the day by evergreens.

Now, when some of you have got a nice plant-garden under some tall branching shade-trees, please invite me to come and see you. Just now I am getting greatly in love with *strawberries* in our rich plant-beds. With plenty of water and plenty of manure I can make them do just what I want, even through the hottest part of summer; and if you want to raise nice strawberry-plants for sale, the plant-beds are the place to do it. If you have exhaust steam that you can run under some of your plant-beds, all the better.

The strawberry-plants I got of you last fall were so fine that several have asked me about you, as they wish to deal with so honest a shipper.

S. S. FETHEROLF, P. M.

Palestine, Ohio, April 15.

THE BEAN CROP, ETC., IN FLORIDA, IN SPITE
OF THE BLIZZARDS.

Mr. Root:—You remember the 7th of February every thing was killed. We thought it of little use to try again after being frozen out twice in one season; but one of my neighbors had 32 lbs. of seed beans on hand, which he concluded to eat to save them. I induced him to sell them to me, and I planted them Feb. 12. I have shipped 78 crates to New York, picked from this 32 lbs. planting, and shall probably get 40 more. We have a good crop of Irish potatoes, which we sell here on the river for \$2.00 a bushel. Our table is well supplied, and has been for two weeks, with cabbage, summer squash, Irish potatoes, string beans; and radishes and lettuce for the last month; so you see we do not have to wait long here, even if we do lose all by a freeze, which does not happen more than once in about ten years, and this the hardest in fifty years. H. T. GIFFORD.

Ver0, Fla., April 22.

ELECTROPOISE, OXYDONOR, ETC.

A PLEA ON THE OTHER SIDE OF THE CASE.

Bro. Root:—I see you have inserted in GLEANINGS several notes condemnatory of the Oxydonor (including it with the Electropoise). Now, may I not ask if you are not talking too fast, and perhaps condemning a thing which you may not understand because you do not see *how* it can be useful because it does not coincide with what has been used in the past. Is it so perfectly impossible that there shall be any new discoveries made in science? and is it not possible that this shall be one? Other discoveries have been ridiculed in the past, and no doubt will be in the future.

I send herewith a circular of the Oxydonor Victory. Please look it over, and decide in your mind whether you can believe that all these certificates, over 250, are either frauds, or have they been relieved or cured all by the powers of their imagination? If you had advised your sick friends to go direct to the Lord Jesus Christ, the great physician, for healing, rather than depend on Electropoise or Oxydonor, I should not have said one word more than "Amen." A. H. VAN DOREN.

Hammonton, N. J., April 19.

My good friend, I should be very glad indeed if it were possible that these people have made a new discovery. Yes, new discoveries are being made in science every day; but it is not possible that some new discovery may decide that 2 and 2 make 5, instead of the old orthodox way, 2 and 2 make 4. Another thing, you confound legitimate discovery with fraud and deceit. In regard to the 250 testimonials, it not only makes it sadder but more deplorable. Suppose these people all declared that nailing a horseshoe over a door performed these wonderful cures—would you believe it? Well, Electropoise and Oxydonor are even worse than this, for they claim to be scientific, and that they have made a discovery; whereas, it is all humbug, cheat, and fraud. These men are hypocrites. Read again what U. S. Chemist, Prof. Wiley, said on page 321 of our last issue.

And now read below the testimony of Pres. Ballantine, of Oberlin College:

Oberlin College, President's Office, Apr. 10.

Mr. A. I. Root, Medina, Ohio:—I agree with you that it is inexcusable for religious papers, or respectable papers of any kind, to advertise such frauds as Electropoise. To take the money of such advertisers is to connive at a confidence game which is all the meaner because practiced upon the sick. If I can co-operate with you in any way in awakening the public conscience it will give me satisfaction. Very gratefully and truly yours,

W. G. BALLANTINE.

It is not a difference of opinion, mind you, in this case; neither is it something these fellows

have discovered that Prof. Wiley and Pres. Ballantine know nothing about. In their circulars and their claims they have invaded the chemist's domain—have talked about taking oxygen from the air with their humbug apparatus. They evidently know too little of chemistry to realize what absurd quackery they are promulgating. In any case, they are guilty of hypocrisy and deceit. They know full well there is no meaning at all, and no science, to the jargon of their circulars. Now, mind you, this is not simply *my* assertion. All learned men and scholars of the present day are in accord with the position I have taken. They *must* stand with me, for there is no other place to stand. I leave it to you—is it probable that these pretenders have discovered something valuable and good? Do men gather grapes of thorns, or figs of thistles? Since you have undertaken to defend these things, I wish you would turn to page 274, where I quoted from the Oxydonor circular, and answer me as to whether there is sense or science in what I quoted.

I thank you for your concluding words. You are aware, friend V., that I do, in every issue of our journal, exhort all mankind to turn to the Lord Christ Jesus; but should I be called upon to stop a thief in the streets, or to arrest a midnight assassin, I should hardly think it worth while to exhort the thief or assassin, in the same breath, to turn to Christ. Should I not, rather, call upon the officers of the law to arrest him and put him safely in prison, and then sit down by his side and exhort him to lead a different life?

I have looked the Oxydonor circular, which you were so kind as to send, all over, and I confess the testimonials are astounding; but, dear friends, have you not noticed testimonials are now floating for almost every thing? And they are getting men with "Rev." attached to their names to indorse it. If you go among the heathen you could, no doubt, get thousands of testimonials as to the efficacy of their gods, made of wood and stone; but it would not, in your opinion, help your faith in those gods; on the contrary, it would sink your faith in those who were so foolish. If Oxydonor and Electropoise shall be the means of waking people up to the absurdity of this whole matter of being cured by every new thing that turns up, no matter whether it has sense or science either to back it, then I grant you some good will be done. If these men have made a discovery, why do they not come forth boldly, and proclaim it to the scientific world? They *dare* not do it. I do not think I have ever met a man who had the cheek or hardihood to stand up before intelligent and educated people, and attempt to palm off such ridiculous stuff for truth or sense. I should pity a man who would even attempt it.

On page 333 we gave the names of four religious papers that would not accept advertisements of Electropoise. There was a fifth one in this group—the *Outlook*; but before we went to press a late copy was received containing a large advertisement of the thing. Of course, the *Outlook* was taken out. As we go to press we find the following in *Electricity* for April 24:

For a journal to assist in the promotion of a gross swindle, and to accept the money of a swindler as a consideration for that assistance, precludes the possibility of such a journal, or the clergyman conducting it, doing successful missionary work among those who know the facts, and there are thousands. We may add that we have the names and addresses of six members of Plymouth congregation who state that they were humbugged out of the price of an Electropoise through seeing it advertised in the *Outlook* some months ago.

I will add here that the editor of the *Outlook*

is the Rev. Lyman Abbott, now pastor of Plymouth Church, Brooklyn, N. Y., the pulpit formerly occupied by the late Henry Ward Beecher.

A. I. R.

TOBACCO AND SCHOOLTEACHERS, ETC.

Your little extract from the *Rural New-Yorker*, in the issue for Apr. 15, induces me to relate the following: When I read that article in the *Rural* I just wanted to give the editor a good old-fashioned handshake and tell him that I had once been in just that predicament. When I began taking GLEANINGS, in 1887, I did not like the tobacco articles, and I fancied A. I. Root was meddling with something that was not in his line. I was teaching, and was using tobacco on the sly, for you see my guilty conscience would not let me be bold about it. By and by, when the State made a law that the evil effects of alcohol and narcotics should be taught in our common schools, our examiners went one step further and would not grant a certificate to any one who used tobacco. This question was asked both lady and gentleman applicants at first; but at present males only are put through the test. You see, it was hardly in harmony with our progressive age for an examiner to look a fair young lady in the face and say, "Do you use tobacco?" Imagine the embarrassment for both. Well, when the examiners made the new ruling I didn't like to give up teaching, so I quit chewing, and resolved to smoke occasionally, generally in the evening, just before retiring. Now, the funny thing about this is, I had imagined I couldn't live without my quid, and I am surprised now to look back and see how soon it was forgotten; but about one night every month or so I dream of having my quid in my mouth; and while the dream lasts I suffer the old anguish and torment to be loose from my old bondage, and I tell you it is a relief to awake and find "it's all a dream."

The smoking was continued till a year ago, when a young lady became an equal partner. The smoking seemed to poison my system to such an extent that, during the night, so much of it was given off that she awakened every morning with a heavy headache. The smoking was stopped, and to-day I am free from a slavery that had me once in an iron grasp. Last winter one of my boys said, "Teacher, do you use tobacco?" I pleasantly replied, "I am free from the habit; and, God helping me, I am ever going to remain so." The supreme satisfaction of being able to say conscientiously what I did to him rewarded my effort. "For surely there is no excellence without great labor."

DR. J. Q. MULFORD.

Lebanon, O., April 19.

BEST ON EARTH.
WILLIAMS AUTOMATIC REVERSIBLE
HONEY - EXTRACTOR.

Perfect in principle and workings. Here is what the veteran bee-keeper, N. E. France, of Platteville, Wis., says of it: "I consider the Williams Automatic Reversible Extractor head and shoulders above any I have ever used, and, furthermore, consider it the BEST on the market." Mr. France produces extracted honey by the carload, so he is good authority on extractors. For price list No. 1 of Extractors, choice Italian Bees, Queens, etc., address

H·O·N·E·Y!

If we would be successful in the production of honey it is of vital importance

that our queens be first-class. After an extended experience with the different races of bees brought to this country, I am led to believe, all things considered, that these direct from Italy have never been improved upon. Large yellow prolific queens from imported mothers, mated to drones of imported stock from a different source, securing a direct cross. Untested, ready May 25, 75c; 6, \$4.25; 12 for \$8.00. Select untested, \$1.00. No disease.

L. H. ROBEY, Worthington, W. Va.

Given Foundation

Ready for Delivery.

We are now making, as previously announced, Given foundation on rolls. We can supply the product at the same price as the regular wax. Customers who desire a small quantity to experiment with can have a little added to the regular foundation if they will so specify in their orders. We neither indorse nor condemn it, but hope it will be tried sufficiently to test its merits. The surplus Given has extra thin bases. The A. I. Root Co., Medina, O.

Queens, Either 3 or 5 Banded.

After May 1st, 75c; 6 for \$4.25. Nuclei cheap. Also poultry eggs for hatching, 50c up. Send for catalogue. Send your orders now. Can please you.

Best ~ Goods

At lowest prices are what we are all after. The quality of Cary's goods has never been questioned. His X X white thin foundation and polished one-piece sections are the finest on the market. His bees and queens are from the best strains, and reared and shipped in the way that long years of experience have shown to be the best.

He has the largest stock of BEE-KEEPERS' SUPPLIES in New England; and as to prices you have only to send for a catalog and compare them with those of other dealers.

To those living in the East, there is the still further consideration of low freight rates. Address

W. W. CARY,

COLRAIN,

MASS.

☞ In responding to this advertisement mention GLEANINGS.

W. O. Victor, of Wharton, Tex., took

45,000 Lbs. of Honey in 1894.

He offers Italian Queens—good, old-style honey-queens—untested, first order, to any address, at 50c each. Also bees in any quantity; 450 colonies to draw from. Root's goods constantly in stock. Prices to suit the times. Buy near home, and save freight.

☞ In responding to this advertisement mention GLEANINGS.

«MONEY-MAKERS»

Are a strain of business Italians that winter in the cold North, and are ready for business, with a bushel of bees, when the flowers bloom. They are gentle and industrious. Queens warranted purely in June. Each, \$1.00; six, \$5.00; doz., \$9.00. Safe arrival and satisfaction guaranteed. Never had any disease.

Address E. F. QUIGLEY, UNIONVILLE, MO.

Please mention this paper.

ITALIAN BEES AND QUEENS.

Ready in May. Queens, \$1.00. Bees by the pound, \$1.00. One-frame nucleus with queen, \$2.00; two frames, \$2.50. Also Barred

Plymouth Rock eggs for setting, \$1.00 per 15.

6-15c

In writing advertisers mention this paper.

BEGINNERS.

Beginners should have a copy of the Amateur Bee-keeper, a 70-page book by Prof. J. W. Rouse. Price 25 cents; if sent by mail, 28c. The little book and the Progressive Bee-keeper (a live progressive 28-page monthly journal) one year, 65c. Address any first-class dealer, or

LEAHY MFG. CO., HIGGINSVILLE, MO.

☞ In responding to this advertisement mention GLEANINGS.

MAPLE SYRUP.

We have not been able to secure enough maple sugar this spring to fill our orders; but we have an oversupply of syrup which we offer at \$1.00 per gal., or \$9.00 for 10 gallons. It is of unusually fine quality, and this price is lower than heretofore quoted.

CARLOAD SHIPMENTS.

During the past month we have shipped a carload to G. G. Wickson & Co., Los Angeles; another to the same firm at San Francisco; one to Barteldes & Co., Denver, Colo.; one to W. K. Ball, Reno, Nev.; and a car of hives and cantaloupe-crates to Rocky Ford, Colo. As we go to press we are also preparing a second car of export orders, the larger part of which is for Hebblewhite & Co., of Sydney, Australia. We are also shipping a carload to Buell Lamberson, the successor of F. L. Posson & Son, at Portland, Ore.

BEESWAX MARKET.

We find that, since the first of Jan., 1895, we have bought over twelve tons of beeswax, and we now have a pretty good stock on hand. At the rate foundation is going out we shall need it all and more. With the opening of spring the offerings of wax in the principal markets are getting to be more plentiful, and we do not look for any higher prices. The mortality of bees in many localities the past winter, no doubt serves to increase the supply of wax. Until further notice we will pay 28c cash, 31 in trade, for average wax delivered here. We feared that it might be necessary to advance the price of foundation again. While we have made an advance in the wholesale price during the past month, we have not advanced the retail price, and trust it may not be necessary during the remainder of the season to do so.

REVISED LIST OF OLD-STOCK SECTIONS.

Quite a number of sizes of old-stock sections offered a month ago have been sold. The revised list is as follows; and the price while they last is \$2.20 per 1000; 3000 for \$6.00; 5000 for \$9.00, or 10,000 for \$16.00.

80,000	4 1/4 x 4 1/4 x 1 1/2,	open top and bottom, extra pol'd.
12,000	" "	" " " " open four sides.
7,000	" "	" " " " x 1 to ft., closed top.
2,000	" "	" " " " " " open four sides.
4,000	" "	" " " " " " x 1 1/2 closed top.
3,000	" "	" " " " " " open four sides.
8,000	" "	" " " " " " x 1 1/2 open 4 sides.
35,000	" "	" " " " " " open top, new-stock cream.
22,000	" "	" " " " " " 2 cream, open four sides.
22,000	" "	" " " " " " x 2, cream, open top, new stock.

To those who can use 1 1/2-inch sections, the above is a special bargain, as they are polished, and first-class in every respect; but we have too many of that width, and desire to reduce our stock.

AGENCY AT PORTLAND, ORE.

Owing to difficulties in the corporation of F. L. Posson & Son, at Portland, Ore., a receiver was appointed early in February. About a month ago Buell Lamberson bought the business of the former company, and came east to complete arrangements for the agencies formerly held by Posson & Son. He spent two days here at Medina, and we have closed a contract with him for the sale of our goods in Oregon and Washington, and are shipping an assorted car to replenish the depleted stock.

Mr. Lamberson is a man of good business ability, with considerable experience, having been fifteen years in Portland, where he is quite well and favorably known, especially in the hardware trade. He retains five of Messrs. Posson & Sons' principal clerks, who have a knowledge of the requirements of trade in our line, so that we can cheerfully recommend the new firm to those in need of bee-keepers' supplies in the Northwest.

THE GAULT RASPBERRY.

We have still a good supply of the Gault raspberry, although the demand has been enormous for them during the past ten days. Remember, the

price at the nurseryman's is 50 cts. each; but any regular subscriber of GLEANINGS—that is, somebody who has paid up or expects to pay up soon—may have one plant postpaid by mail for only 25 cts. Any rich spot in the garden, or even a corner not more than a yard square somewhere in the doorway, will give you room for one of these beautiful plants. If you want to see it do its best, I would advise you to dig down deep and make the ground rich. Have it where you can water it when needed, if the weather is very dry. No plant can furnish the enormous quantity of juicy fruit that this one does, without the wherewith in the shape of food and drink. Besides getting the fruit, you can get a dozen more plants in the fall that will, very likely, be worth 25 cts. each a year from now.

DWARF ROCKY MOUNTAIN CHERRY.

A year ago I purchased three of these of Storrs & Harrison, of Painesville, O., for 50c apiece. They seemed very hardy, and made quite a good growth last season. This morning I was agreeably surprised to find that one of the three, although less than 2 1/2 feet high, is covered with blossom-buds. Now, even if the fruit should not be quite equal to the advertisement, I am well satisfied with my investment, to get a plant so strong and thrifty that it will be full of bloom at one year from planting. The catalog tells us, "the size averages somewhat larger than the English morillo. Its flavor is similar to that of sweet cherries."

LATHYRUS, AGAIN.

To-day, April 26, we are taking up our plants and moving them to the field. I was astonished to see the nitrogen-nodules strung along on the little rootlets, like beads on a cord. It is now satisfactorily settled that all leguminous plants—peas, clover, etc., that produce these nodules or little white knobs the size of a pinhead on their roots, have the faculty of taking nitrogen from the atmosphere. That is why clover is worth more than any other plant to plow under. At the Experiment Station in Florida they showed me these nodules on their leguminous plants. Well, I never saw any thing like the number on our lathyrus. The roots go down so deep that my stalwart friend "Ben" said it was too much work to try to dig them without breaking the roots off. At its present stage, with the foliage only a few inches in height, I am sure cows and horses will take it as readily as they will any of our clovers. When it gets to be tall and strong it may be different. If you wish to see one of these plants, foliage and all, we will mail you one for 5 cts., or 10 of them for 25 cts. With such a root as they have, I do not know how the plant can fail to grow.

The wonderful power this lathyrus possesses to penetrate a hard and impervious subsoil was shown in digging up a plant an hour ago, that had forced its root absolutely through a piece of partially rotten board that was down in the plant-bed. The root came through on the other side, and went several inches beyond the board; but it was so firmly fastened that the bit of board was carried along and put out with the plant. The roots invariably go straight down; and after they are 6 months old they will, without doubt, be proof against drouth to dry up the plant, or against the effects of frost to heave it out in winter.

HUBBARD SQUASHES.

Hubbard squash has sold, even at wholesale, for from 2 to 2 1/2 cts. per lb. during most of last winter. We ourselves sent to Cleveland again and again, for great big solid Hubbard squash, paying 2 1/2 cts. per lb., or at the rate of fifty dollars per ton; and our Medina people paid from 3 1/2 to 4 cts., without a bit of grumbling. Away down in Florida, northern-grown Hubbard squashes sold for 5 cts. per lb. Why, it is ridiculous—half a dollar for a fair-sized Hubbard squash! What ails the farmers? Of course, it is a little bit of science to keep them from frost and decay away on into January and February. But anybody can do it if he wants to bad enough. Well, Hubbard squash seed is now quoted in the catalogs all the way from 60 to 80 cts. per lb. We offer it in our price list at 50 cts. per lb.; and farmers and gardeners pay these prices for seed almost every year. When we bought those great Hubbard squashes in Cleveland for 2 1/2 cts. per lb., I told the man on the wagon he might sell them a cent a pound cheaper if the purchaser would give us back all the seeds; and in this way we got quite

a lot of very choice stock. Just recently one of our bee-keeping friends offered me a big lot of Hubbard squash seed. I did not want so much, but I made him an offer for it. Now, this seed is not cleaned so as to look exactly as nice and white as that we get from seedsmen; but I think it will grow just exactly as well. He is a squash-grower himself, and says he is going to plant largely from the very same lot of seed he sent us; and if you want some of this seed, you may have it at 40 cts. per lb.; 5 lbs. at 35 cts. per lb.; 10 lbs. or over, 30 cts. per lb. If wanted by mail, add 10 cts. per lb. for postage and packing. As there is no particular hurry about getting the seed into the ground, if you choose you can order a five-cent package for sample, before you purchase largely. By the way, Hubbard squash can be put in between a great variety of crops that come off early in the season. Our neighbors in the Harrisville swamp plant Hubbard squash between their seed-onions; and as soon as the seed is ripe enough to gather, the ground is cleared off, and the squashes have the whole field. You can do the same by putting them among your early potatoes, early celery, sweet corn, and ever so many other things. Very likely they may not sell for \$50.00 a ton next year; but there is money in Hubbard squashes at even \$20.00 a ton, or less.

SEED POTATOES.

These are all gone except a few barrels of second-size Freemans in excellent condition; peck, 40 cts.; one bushel, \$1.25; one barrel, \$3.00. Also four or five barrels of Rural New-Yorker, a few Lee's Favorite and Early Ohio, and about 50 bushels of Monroe Seedling, all first size. We can still furnish the Craig Seedling, and probably shall have some of them left during the month of May. By the first of June, however, we expect to plant every thing not sold.

We have a nice lot of Mammoth Russian sunflower seed that we can furnish at 8 cts. per lb.; 5 lbs. or over, 6 cts. per lb.; 10 lbs. or over, only 5 cts. If wanted by mail, add 10 cts. per lb. for postage and packing.

KIND WORDS FROM OUR CUSTOMERS.

FREEMAN-POTATO REPORT.

Although it was a poor season for potatoes, I raised 32 lbs. of very nice potatoes from the one pound I got of you. JOHN D. WISE.
Camden, Ind., Jan. 26.

I sent you Oxydonor circular, and now ad't in the *Endeavorer*, that you may place it with Electropoise. Thanks for your exposé of frauds. Go for the religious papers that are leagued with Satan to cheat their patrons and lessen their own influence for good. Our own New York *Christian Advocate* refers to Electropoise as fraudulent. Oh for moral stamina in pulpit and press to kick the Devil wherever he is found! Oh for a Christian manhood that confers not with flesh and blood, but stands for the right, without regard to consequences.

Philipsburg, Pa., Feb. 19.

JOHN D. GILL.

I enjoy very much your writings on your Florida trip. I lose about a third of my bees, but my neighbors lose all. Oh, yes! what is the matter with Bro. Rambler, on page 166—high hat, stand-up collar, and store clothes from fire down town? Hah! I often feel very sorry for him, living alone in this world.

I hope you will not stop your Scripture talk. In fact, every thing in GLEANINGS is so interesting to me that, when I take it up, I can hardly lay it down until I have read it through. D. N. RITCHIEY.

Blacklick, O., March 30.

KIND WORDS FROM A QUAKER.

A. I. Root:—A few years ago I read in GLEANINGS thy plan for warding off sick-headache. I was so much pleased with it that I determined to write at some future time, thanking thee for the manliness to publish such an article—feeling sure that it was a pure and noble philanthropy which prompted it. To what extent thy readers will avail themselves of the information contained therein given, I do not know—I fear not much. People like to be humbugged. But that is not thy fault; and if the publica-

tion of such principles as given in the article in question are not directly beneficial to a large number of people, it will at least do much toward educating the people to a reform in medicine, which must come through an imperative demand from the people and not through the schools of medicine of their own volition; because, when men get both honor and emolument, with little labor, they will not "kill the goose that lays the golden egg."

I will say, concerning thy treatment for prevention of sick-headache and other forms of disease as well, "that ought ye to have done, and not leave the other undone." Give the patient hot water to drink (I mean as hot as can be used comfortably)—hot-water baths (or, better, vapor baths), proper food and exercise, in addition to thy prescribed course, and we can cure most forms of disease that are curable, and they are nearly all curable.

I myself was educated in the physio-medical ("steak doctor") faith. We are like the old toper. He said, "Ever since the flood, water tastes of drowned sinners. I always put a little su'thin' in mine." We always "put a little su'thin' in" our hot water; but water in its various states is one of nature's best. I have no fight with the hydrotherapeutic (or water-cure) system; but I detest the poison and humbugging system.

I thank thee for being a man with the courage of his convictions. There are more of that stripe needed. There are many lines on which people need to be educated. Just now we have started in a wrong direction—I mean military education in school and church. The National W. C. T. U. has 46 departments of education and training organized, and military is not one of them. I have a sneaking kind of idea that woman suffrage and equal rights is one of the most important if not the most important of the 46. PAUL TOMLINSON, M. D.

Cedarville, O., Dec. 10.

Carniolans Imported, \$5 each.

Bred in 1894 at the most elevated point among the Carnic Alps where bees are kept. Untested daughters of these, \$1 each; 12 for \$10. Tested daughters producing gray bees, \$2 each; 12 for \$18.

Crane Smoker 1895 Pattern.

This excellent smoker was introduced some two years ago, since which time it has worked itself rapidly into popular favor.

Patented March 12, 1895.

Its Distinctive Feature is the Crane Valve, by which the full force of the bellows is secured without waste, and by which also smoke is prevented absolutely from going into the bellows.

The Legs are of Skeleton Malleable Iron, contracted at the feet so as to be out of the way of the fingers in handling, and are secured to the bellows by bolts instead of screws.

The Shield is of Light Corrugated Tin, and bags next to the bellows, thus giving ample protection from heat.

The Cone Top easily tilts back for replenishing the smoker, and is secured by a malleable-iron hinge, the working parts of which are milled so as to insure accurate adjustment to the stove or cup.

As to Fuel, it will burn any thing, including Soft Coal, Stovewood, Planer-shavings; and it makes no difference how much the latter may be crammed down in the cup, there will be the same strong blast as before.

Price, 3½-inch barrel, \$1.85, post-paid; or \$1.50 by fgt. or exp.

"GENTLEMEN: Regarding prospects for the coming year, would say, we hope to double our last year's output of Aermotors, or, at least, as we have done in the past, sell twenty-four out of every twenty-five windmills that are sold. Since commencing the sale in 1893, WE HAVE SOLD ABOUT

500 AERMOTORS

We do not attribute this fairly good record entirely to our efforts, but to the superiority of the goods which you make. BURRELL & DAVIS, Urbana, Ill., February 13, 1895."

GENTLEMEN: We bought and put up Aermotor No. 2, and out of the first fifty which you made we had thirteen. Since that time we have sold about

400 AERMOTORS

in our small territory is represented the history of the Aermotor and the Aermotor Company from the beginning to the present hour. That history is one of unbroken triumph.

Aside from the Aermotor other windmills put up enough with which to show the infinite superiority of the Aermotor in design, finish, full galvanized iron, and ability to run when all others stand. We should have sold more, supplied with wind power, but it being only 60 miles years been the battle ground largest, best known and panies, all being located MUCH OF OUR BUSINESS PLACING WOODEN AND TORY WHEELS WITH you have during the past vious year's record by you expect to double your coming year. Count on us for the Aermotor never stood farther above all competitors in reputation and in fact than to-day. SUTTS & BAIGER, Marengo, Ill., February 25, 1895." In another Aermotor advertisement, which every one should read, we offer for

\$7.50 A \$15

three way force pump. All dealers should have it or can get it to sell at that price. All Aermotor men will have it. In still another ad. appears our offer of galvanized steel tanks at 25c. per gallon. They neither shrink, leak, rust, nor make water taste bad.

HONEY COLUMN

CITY MARKETS.

KANSAS CITY.—Honey.—The stock of comb honey is large; market well supplied. Fancy white 1-lb. combs, 13; amber, 11. Receipts of extracted light; white, 7; amber, 5½@6; Southern, 4½@5. Beeswax, 29.
HAMLIN & BEARSS,
Kansas City, Mo.
May 8.

CHICAGO.—Honey.—We report our market well cleaned up on fancy white comb honey in 1-lb. sections. A neat package and a fancy article would sell quickly at 14c. No. 2 comb, or dark, would not sell at over 10¢@11. We report better inquiry for extracted, at 5¢@7, depending on quality. Beeswax selling at 30c.
S. T. FISH & CO.,
189 South Water St., Chicago, Ill.
May 7.

ST. LOUIS.—Honey.—We have fairly good trade in honey, and on account of early receipts of new crop expect an improvement. We quote comb, 10¢@13; extracted, in cans, 6½¢@7; in barrels, 5¢@5½. Prime yellow beeswax, 27¢@27½.
D. G. TUTT GROCER CO.,
St. Louis, Mo.
May 8.

KANSAS CITY.—Honey.—The demand for comb honey is light. We quote No. 1 white comb, 13¢@14; No. 2, 1-lb., 12¢@13; No. 1 amber, 11¢@12; No. 2, 10; extracted, 5¢@7. Beeswax, 25.
C. C. CLEMONS & CO.,
Kansas City, Mo.
May 8.

DETROIT.—Honey.—Best white comb honey 13¢@14, with little in sight. Dark, unsightly lots almost unsalable. Extracted, 6¢@7. Beeswax, 28¢@30.
M. H. HUNT,
Bell Branch, Mich.
May 9.

CLEVELAND.—Honey.—Our honey market is very slow. No. 1 white, in 1-lb. sections, 12c; No. 2, 10; extracted, No. 1 white, 6¢@8. There is a fair demand for extracted, but no call for the comb. Beeswax is selling at 28¢@30.
WILLIAMS BROS.,
80 & 82 Broadway, Cleveland, O.
May 7.

BOSTON.—Honey.—We quote our market at 13¢@14 for best 1-lb. comb honey, and 5¢@6 for extracted, with light demand.
E. E. BLAKE & CO.,
Boston, Mass.
May 8.

PHILADELPHIA.—Honey.—Comb honey finds little or no sale now in large city. Extracted is selling freely. We quote comb, 9¢@11; extracted, 5¢@6. Beeswax, 31.
WM. A. SELSER,
10 Vine St., Philadelphia, Pa.
May 8.

MILWAUKEE.—Honey.—Since our last there has not been much change on this market on honey. The receipts have been good, and our supply is of general good quality. The receipts of late have rather exceeded our sales, and market now is somewhat easy and sales slow. Can quote best 1-lb. sections, 15¢@16; second, 13¢@14; third, 10¢@13. Extracted, in bbls. or kegs, white, 7¢@7½; dark, 6¢@8; in pails, white, 8¢@8½. Beeswax, 26¢@28.
A. V. BISHOP & CO.,
Milwaukee, Wis.
May 8.

DENVER.—Honey.—There is an improvement in our market for both comb and extracted honey. We quote No. 1 comb, in 1-lb. sections, at 11½¢@12½; No. 2, 9¢@10. Extracted, No. 1 white, in 60-lb. cans (2 in a case), 6¢@7. We are short on No. 1 comb, and could handle a quantity to advantage.
R. K. & J. C. FRISBEE,
Denver, Col.
May 9.

CHICAGO.—Honey.—The amount of comb honey that is sold during this month is very small, consisting of a case now and then, so that the market fluctuates but little. Sales are made at 14c for best grades now obtainable, all fancy lots having been disposed of. Extracted is very slow of sale, with prices flexible within a range of 5½¢@7c, according to quality, flavor, color, and package. Beeswax sells on arrival at 30c when of average cleanliness.
R. A. BURNETT & CO.,
163 So. Water St., Chicago, Ill.
May 7.

ALBANY.—Honey.—Small lots of comb honey continue to arrive, but the demand is very light, owing to the lateness of season and warm weather. Prices range from 8¢@12c per lb. No beeswax on hand.
CHAS. McCULLOCH & Co.,
Albany, N. Y.
May 8.

BUFFALO.—Honey.—No material change in the honey-market. Fancy is moving slowly at 13¢@14; choice, 11¢@12; commoner grades are hard to sell, and a few tail ends remain unsold.
BATTERSON & CO.,
Buffalo, N. Y.
May 7.

NEW YORK.—Honey.—We quote beeswax at 32c per lb. Supplies are small, demand moderate.
F. G. STROHMEYER & H. ARPE,
New York, N. Y.
May 9.

ALFALFA IN ARIZONA.—We will sell you alfalfa honey F. O. B. Phoenix at 4½c in 1000-lb. lots or more. Less than 1000 lbs. at 5c in five-gallon cans. Car lots a specialty.
J. P. IVY,
Secretary Bee-keepers' Association,
Phoenix, Maricopa Co., Arizona.

ALFALFA HONEY, very white, thick, and rich. Two 60-lb. cans at 7c. Same, partly from cleome (tinted), 6c. Samples, 8c.
OLIVER FOSTER, Las Animas, Col.
May 8.

No. 1 extracted honey in 50-lb. pails at 7c per lb.—
J. B. MURRAY, Ada, O.

BEST ON EARTH.

WILLIAMS AUTOMATIC REVERSIBLE

HONEY - EXTRACTOR.

Perfect in principle and workings. Here is what the veteran bee-keeper, N. E. France, of Platteville, Wis., says of it: "I consider the Williams Automatic Reversible Extractor head and shoulders above any I have ever used, and furthermore, consider it the BEST on the market." Mr. France produces extracted honey by the carload, so he is good authority on extractors. For price list No. 1 of Extractors, choice Italian Bees, Queens, etc., address
VAN ALLEN & WILLIAMS, Barnum, Wis.

GOLDEN QUEENS Bred for business. Untested, May, 70 cts. each; 3 for \$2.00. Tested, \$1.00 each. Fine breeders, \$2.00 each extra. Select straight 5-banded breeding-queens, \$4.00 each. To all new customers one **GOLDEN QUEEN** for 50 cts. Satisfaction and safe arrival guaranteed.

BEGINNERS.

Beginners should have a copy of the Amateur Bee-keeper, a 70-page book by Prof. J. W. Rouse. Price 25 cents; if sent by mail, 28c. The little book and the Progressive Bee-keeper (a live progressive 28-page monthly journal) one year, 65c. Address any first-class dealer, or

LEAHY MFG. CO., HIGGINSVILLE, MO.

In responding to this advertisement mention GLEANINGS.

TESTED QUEENS

Are usually sold for \$2.00. I will explain why I wish to sell a few at less than that. As most of my readers know, I requeen my apiary each spring with young queens from the South. This is done to do away with swarming. If done early enough it is usually successful. It will be seen that the queens displaced by these young queens are never more than a year old; in fact, they are fine, tested, Italian queens, **RIGHT IN THEIR PRIME**; yet, in order that they may move off quickly, and thus make room for the untested queens, they will be sold for only **ONE DOLLAR**. Or I will send the **REVIEW** for 1895 and one of these queens for only \$1.75. For \$2.00 I will send the **REVIEW**, the queen, and the book "Advanced Bee Culture." If any prefer the young, laying queens from the South, they can have them instead of the tested queens, at the same price. A discount on large orders for untested queens. Say how many are wanted, and a price will be made. Orders can be filled as soon as it is warm enough to handle bees and ship queens with safety.

W. Z. HUTCHINSON, Flint, Mich.

Ten Weeks for Ten Cents!

For ten cents (in stamps or silver) the **American Bee Journal** will be sent for **Ten Weeks** (10 numbers) to any one who is not now a subscriber. A ten weeks' trial is a fair trial, and ten cents is a small price for the testing. Better accept this offer at once, or at least send for a free sample copy of the **Weekly American Bee Journal**. GLEANINGS IN **BEE CULTURE** A JOURNAL DEVOTED TO BEES AND HONEY AND HOME INTERESTS. ILLUSTRATED SEMI-MONTHLY Published by THE A. ROOT CO. \$1.00 PER YEAR MEDINA, OHIO.

Vol. XXIII.

MAY 15, 1895.

No. 10.

STRAY STRAWS FROM DR. C. C. MILLER.

A GLORIOUS SPRING for bee-keepers.

THAT FEEDER of H. K. Boardman is hard to beat as an entrance-feeder.

CRIMSON CLOVER, according to J. C. Smith, in *American Bee Journal*, does best sown with buckwheat.

TEN FEET OF SNOW covered four hives for more than eleven weeks, and the bees came out all right.—B. B. J.

DR. J. P. H. BROWN, of Augusta, Ga., has taken charge of the Southern Department in the *American Bee Journal*. Good man.

I CAN NOT RESIST the impression, from all I've read in *GLEANINGS*, that A. I. Root doesn't entirely approve of Electropoise and Oxydonor.

THE LIME as a honey-tree, is a little confusing. Sometimes it means the linden, or basswood, and sometimes it means a small tree much like the lemon.

STATISTICAL REPORTS received by *GLEANINGS* seem encouraging, and yet elsewhere reports are quite discouraging, losses even reaching 50 and 80 per cent.

BASSWOOD, says Dr. Brown, *American Bee Journal*, is rarely found south of latitude 33°, and then only on low land. The European variety does better than the common.

A NEW SMOKER, Zaehring's, is described in German bee-journals. It's nothing more nor less than an atomizer, or sprayer, with a big rubber ball. But it's well spoken of.

THE ANCIENT ROMANS believed that bees originated from the decaying carcasses of cattle. [There was a good bit better reason for believing this centuries ago than for putting faith in Electropoise and Oxydonor.—ED.]

GRAVENHORST says that young queens that do not issue with a swarm, but merely emerge

from the cells and remain in the hive, are, as a rule, much later in becoming fertile than those issuing with a swarm. He prefers the latter queens.

DOOLITTLE defines his position as to spreading brood, in *American Bee Journal*. He would spread only when the queen does not keep filled with brood the combs well covered by bees. That's all right, isn't it? [Yes, sir; and when that rule is followed, no bad results will follow.—ED.]

FARMER HARDWEAR at the telegraph office.—“How much will you charge to telegraph my son \$300 at college?”

Operator.—“Two dollars.”

Farmer Hardwear.—Gosh! that's cheap! Yer's the \$2. Send it quick as lightning.”—*Chicago Record*.

“MELILOFUS is one of the very few plants which are able to draw their supply of nitrogen from the air; and hence by and through its biennial decay it furnishes the most valuable and most expensive factor in commercial fertilizers free of cost, and in the best form.”—*Prof. S. M. Tracy*, Director Miss. Exp. Station.

DOOLITTLE's observation, p. 361, as to colonies deserting in spring, leaving nice brood and plenty honey, agrees with mine, and in every case I think there has been more brood than the bees could cover. Is it because the bees have become so reduced in numbers that they desert rather than stay and see that brood die?

DWARF ROCKY MOUNTAIN cherry promises well with you, friend Root, but it may be well to add a caution. It was boomed at the World's Fair, but I heard a company of horticulturists denounce it as a humbug, and if I remember rightly the veteran Edgar Sanders said it formerly grew wild on the lake shore near Chicago.

A ASTOR, in *Revue*, says his hives containing 6770 cubic inches inside the frames are too small. Dzierzon, in his “Rational Bee-keeping,” says, “A space of about 3000 cubic inches will be sufficient in most districts; neverthe-

less, a space of 5000 to 6000 inches will do no harm, if there be no difficulty in partitioning off the superfluous space." Quinby thought 2000 was enough for the brood-nest. An eight-frame dovetail has 1579 inches; a ten-frame, 1964.

GRAVENHORST advises thus with respect to after-swarms. Wait till the first after-swarm issues; cut out all queen-cells, and return the swarm. Friend Gravenhorst, I believe some who desire no increase might carry the plan still further. Kill or remove the queen of the prime swarm, letting the swarm return, then treat the second swarm as you advise.

OVEREATING shortens a man's days in more ways than one. It shortens the number of days, and it shortens the number of waking hours in each, for he must sleep off the effects of the surfeit. [I wish this same sensible good advice had been given me years ago. All the same, I am and have been profiting by it for the last six months. Better? Of course, I am. I believe at least half the ailments are indirectly traceable to this one thing.—ED.]

UNITING. "A colony having a laying queen will accept without any trouble any colony which has been queenless for at least 24 hours. Consequently, if you want to unite two colonies standing side by side, deprive one of its queen; and the next day, or the day following, hang the combs with adhering bees of the one colony in the second story of the other colony, immediately above the bees below, and remove the empty stand."—C. F. Muth, in *American Bee Journal*.

"SEPARATING SWARMS when two or three cluster together.—If for three swarms, tier up three hives with an entrance to each on a stand; raise the bottom hive an inch from the board to give the bees room to go in; shake the bees in front of the hives, stop the entrances to the two upper ones, and let them settle for half an hour; then take the top hive and put it on a stand; put the second on another, and let the bottom one remain, and your three swarms and queens are separated."—P. D. Wallace, in the *American Bee Journal*.

"WE BOOMED the T-super arrangement in our 1895 catalog harder than ever, putting in a nice wood-cut."—GLEANINGS, p. 394. Yes, and right under that nice cut you say, "We consider the section-holder superior." How's that for booming the T super? No wonder your packers "hardly know what it is." And then you want to make out an old stove fits me! I'll fit you in an old stove if you don't look out. [The quotation taken alone as above doesn't boom the T super very much. But in the same paragraph we refer to others, including yourself, who think the T super the better. The paragraph as a whole gives it a good prominence. Perhaps "boom" was too strong a word.—ED.]

FEEDING BEES.

FEEDING BACK TO HAVE UNFINISHED SECTIONS COMPLETED.

By H. R. Boardman.

The last few years have brought to the surface considerable discussion in regard to this kind of feeding, and a diversity of opinion still prevails among very good bee-keepers in regard to it. About the only important thing left yet unsettled is, whether it pays or not. There have been some figures given the public, upon this question. It is said that figures will not lie. I can not deny it; but they are sometimes manipulated so as to be misleading. I will give you the benefit of my experience and opinions, without figures.

The object sought is, to follow some plan by which the feed will be stored in the sections as much as possible. This the bees are not disposed to do so long as they have room in the combs near the brood-nest. I have tried two plans. One is, to deprive the brood-hive of combs as far as possible, and thus compel storing in the sections. The other is, to deprive the colony of a brood-nest, making them queenless, with only enough brood to raise a queen. In the first place, I put a swarm upon empty frames with starters only, by shaking them out (or drumming out) from a populous colony, leaving the old colony to raise a young queen. I feed immediately; and as soon as the queen begins laying in the newly started combs I put on the sections and continue feeding rapidly for 25 days. This gets most of the feed into the sections, excepting that used for brood and comb-building, and a little stored outside of the brood-nest in the new combs. These combs will be nice worker-combs mostly, and will, I think, be worth all they cost.

QUEENLESS COLONIES.

The second plan—that of depriving the colony of a brood-nest by making it queenless—throws the bees all, or nearly all, into the sections, where there is comb already built, and they will continue the work there mostly, as there seems to be no inducement to build comb in the brood-chamber. The plan I have followed in my experiments is the same as already given, except that I remove the queen back to the old colony as soon as a few eggs appear in the newly started combs, sufficient to hold the bees and enable them to build queen-cells. I had great hopes for this plan, and, indeed, it has some advantages. But it must be borne in mind, that, although the bees build but little comb in the brood-chamber, being queenless, the combs will be imperfect, and filled with the feed. To remedy this I cut them out as fast as

built, and allowed the bees to carry back into the sections the honey they contained. But there is so much upon the unfavorable side of this question that I am not prepared to recommend this kind of feeding as very practical, and I think it would be most likely to prove unprofitable. By way of experiment upon a small scale, it is well enough. Very much is to be learned by such experiments. I could give figures upon this kind of feeding, that would show a profit very clearly; but in giving them, many of the unfavorable details would be left out, lost sight of. It involves a great amount of work and care, from beginning to end, and I have nearly always failed in the most important part—that of getting a choice finished product. Unless the sections are unsealed before they are put on they will be finished with a rough and patchy look, and will be, according to my experience, more or less stained with propolis, which gives them an untidy appearance.

WHAT TO DO WITH UNFINISHED SECTIONS.

The best and most profitable way for the average bee-keeper to dispose of unfinished sections, I am convinced, is to extract all that will not sell as second grade for as much as extracted honey will bring, and use them for bait sections the next season. There is a value in these nice white combs for this purpose, that is not appreciated by very many.

SUGAR HONEY.

There have been a good many suspicious hints dropped in the past few years about sugar honey. Cheap sugar has been the tempter. But nothing has materialized from these suggestions but talk, so far as I know. I am going to consider only the practical phase of this question, and leave the scientific part to the scientist. So far as feeding sugar to be stored in the sections is concerned, it is sufficient to know that there is no inducement for such a practice. Until bee-keepers have the courage to feed sugar for stores in the brood-chamber to the full extent necessary for that purpose, there is no use in wasting our valuable time discussing the very remote possibilities of sugar honey. It would seem like very poor economy to fill the brood-combs with the choicest honey from the flowers, and the sections with sugar, even if it were practical, when just the opposite is desirable, and much easier to accomplish. It would be somewhat like the economy in dairying, of feeding the cream to the calves and pigs, and saving the skimmed milk for use.

MAKING NEW COLONIES; NATURAL COMBS VS. FOUNDATION.

After the honey season is over, and that mysterious impulse to swarm is abated, new colonies may be made and built up from sugar feed. Natural combs built at this time will be almost entirely free from drone comb, and will compare favorably in perfection with combs drawn from foundation. There is a large force of workers lying idle; and the busy season being

over makes it somewhat of a temptation to do such work at this season. I have thought it just as well to wear these bees out as to let them live in idleness and die of old age, provided, of course, there was any profit in it. I have a good many of these natural combs in use now that I have built in this way in the last few years, and they give very good satisfaction. I reasoned that, with the prevailing low price of sugar, and the high price of wax, together with the late succession of poor seasons, bee-keepers ought to be able to become producers of wax by raising natural combs, instead of consumers by using foundation. I do not really think there is much money in it. I only hope it may help in the sharp struggle for survival, especially in poor localities.

This work gives an excellent opportunity for superseding the old queen—a very profitable work. In any of these operations described, if no increase is wanted the bees may be united back upon the most desirable combs. I have no doubt that new combs are best for building up in spring, but old ones may be better for wintering outdoors.

East Townsend, O.

WHAT CONSTITUTES A GOOD BEE?

NINE POINTS CONSIDERED IN THE ORDER OF THEIR IMPORTANCE.

By S. E. Miller.

What are the essential qualities in a colony of bees? Perhaps it would be hard for all bee-keepers to agree on this subject; but I have given some thought to it lately, and after thinking the matter over I would place the points about as follows:

1. Prolificness of the queen.
2. Honey-gathering qualities of the workers.
3. Hardiness in wintering.
4. Disposition of workers—gentleness, etc.
5. Non-swarming.
6. Comb-building.
7. Longevity of queen and workers.
8. Size of workers.
9. Color.

Probably no one will agree with me in the exact order I have placed the points of excellence, and probably no two bee-keepers would agree exactly. I am not speaking of the manner in which a colony would be judged at a fair; for at a fair they might be judged very unfairly; for at best it is little more than guesswork. The judge, in all likelihood, has no knowledge of the working qualities of the colony, so that size and color would be apt to guide him mainly in rendering his decision.

But what I am speaking of is the colony of bees that will earn dollars and cents for their keeper. And now let me explain why I have placed the points of superiority as shown above. Let us consider the first point. There, I be-

lieve, nearly all will agree with me, that the first essential to a No. 1 colony is a prolific queen that can be relied upon to produce a host of workers at just the time when most needed; and without a prolific queen it matters not how good the workers are. If there are not enough of them we can not expect them to store a large quantity of honey. Having a queen that will place a strong force on the stage of action at the time when most needed, we want that force to get a move on them and roll in the honey while their neighbors are hanging on the shady side of the hive or coming the "washboard act" around the entrance. So we see that, having these two points combined, we come very near having a perfect colony already. But let us proceed to the third point.

Having stored a large quantity of honey this season we want them to do as well next year again; and in order to attain to this end it is essential that they be able to withstand the severe winter weather without having to be put into a feather bed. To those who winter in cellars this point might be considered of minor importance; but we do not all winter our bees in cellars, and probably there are many of us who never will; therefore we want colonies that will pass the winter with the least possible loss in numbers, and come out strong and healthy in the spring.

Fourth, gentleness. No one, I presume, will deny that this is a desirable trait in bees, and probably some would place it above some of the points named above; but should a cross colony, of strength equal to one of a gentle disposition, gather, say, a third more honey in a given time, I believe I would manage to get along with the cross ones for the extra amount of honey they store.

Non-swarming, or the absence of a desire to swarm, is a trait that the comb-honey producer would probably place among the first qualities to be desired; but so long as swarming comes with prosperity and seasons of large crops of honey, and non-swarming is accompanied by failures, I should consider swarming the lesser of the two evils, if swarming may be considered an evil.

Sixth, comb-building. In order to produce a first-class article of comb honey we want bees that will go to work at it in a business-like manner, building straight even combs, and attaching them securely to the sections all around. But as this also depends largely upon the honey-flow and the condition of the colony as well, it can hardly be considered as one of the first essentials of a first-class colony; for, in my experience, almost any fair to good colony will do good work in this line provided there is a sufficient flow of nectar for a number of weeks at a time. As to the whiteness of the cappings, it is merely a matter of fancy; for the honey inside of a comb having a translucent appearance is as good as and often better than that having the whitest cappings. However,

so long as the market demands white combs it is to the bee-keeper's interest to produce such.

Longevity in queens is something to be desired, but is not of such great importance when we consider that every practical bee-keeper can rear an abundance of queens at very little cost; yet a queen that will do good service for three years is worth more than one that wears out in one season, and we should certainly prefer the former to the latter kind. As to longevity in the workers, it seems no one has given the matter much thought or study. No doubt a worker that would live and do good work for sixty days at the season when most needed would be worth more than one that wears out from overwork at from forty to forty-five days; but probably it will be a long time before any one sets up the claim that he has a strain of bees in which the workers live to a greater age than those of the ordinary kind. Probably under the same circumstances—that is, having the same care from the egg to the adult, doing the same amount of work, having the same protection from cold, etc., one worker will live as long as another.

Large size, in both queens and workers, is something we admire; but who would care to have them as large as the fellow said they grew to be in Germany (as large as sheep) if they gather no more than those of smaller size? Yet the fact remains, that the larger bee may have a proportionately longer tongue than the smaller one, so that size should not be lost sight of in breeding for the best.

Color—there is my ninth and last point of excellence. Won't some of the yellow-banders be ready to jump on to me for placing color at the tail end? Probably I should have made ten points, while I came so near it; but I will leave that for some other fellow to put on. Had I mentioned ten points, color would certainly have been the tenth—not that I am opposed to beautiful bees, or that I should not prefer them provided they were as good as their more homely cousins; but really if we had a strain of bees that would gather one thousand pounds of A No. 1 honey per colony in a season, would it matter whether they were brown, yellow, green, or red? Are the fastest trotters the handsomest of the horse kind? Are the prize-winning Jersey cows the prettiest cattle? or have the breeders who bred them up to the high standards of excellence bred for beauty, or for the profit there was in them? If any one can show that color or beauty should be placed above any one of the other eight points I have named, I am ready to give him a cooky; and yet have not many bee-keepers from the Atlantic to the Pacific, from Maine to Texas, been chasing after yellow bands, instead of large crops of honey, for the last three or four years? Nearly all breeders of the so-called golden or five-banded bees claim that their strain is bred for business; but who among them

will stand up and say that, while breeding for yellow bands or solid yellow, he has all the time kept in mind, paid close attention, and given painstaking care to the other eight points of superiority to be desired in the honey-bee of the future? Who is he or she? Where do they live? I hear no answer, but the owl repeats the words—

"Who who—who are you?"

Bluffton, Mo.

[This is another excellent article, and I could not help saying "Yes, yes," to every point friend Miller gave. I wish all bee-keepers, especially queen-breeders, would read this over carefully. Yes, friend Miller, if you had enumerated 100 good points I believe I should have put color at the bottom of them all. It would not do to give it even a favorable position, for then some queen-breeders and some bee-keepers would put it at the top. In fact, I wish color could be buried clear out of sight, and stay there—not that I despise beautifully colored bees, nor that I have any grudge against bee-keepers or queen-breeders who rather favor the yellow bands; but I am afraid color has already had a rather detrimental influence on the real bread-and-butter side of bee-keeping.—Ed.]

Our Hive Symposium.

THE JUMBO SIXTEEN-FRAME HIVE.

ONE LARGE SINGLE-STORY HIVE; SUCH HIVES MANAGED BY A YOUNG GIRL OF 18; QUEEN-EXCLUDING HONEY-BOARDS DISPENSED WITH AND NO SWARMING.

By N. E. Doane.

Mr. Editor:—As you seem to be interested in the item I gave you in regard to the 16-frame L. hive. I will try to tell you more about it. As I make it now I call it the "Jumbo hive." I commenced keeping bees some twenty years ago. I have used the eight-frame L. hive, also the ten, and the Simplicity hive. I commenced with the six-pound box for surplus honey, then used the prize box, in its day; then came the four-piece section and the Heddon case; the one-piece section and the wide frame. All these were used and found good until something better took their place. With me, a few years ago when the bee-keepers of our land were cutting their ten-frame hives down to eight, I cut mine the other way (some of them), and made a 16-frame hive instead. My main reason for doing so at that time was to prevent swarming, and to keep the bees storing honey contentedly throughout the season; but I soon found that a 16-frame hive covered with wide frames, and one extracting-comb, to call the bees up, was no preventive. A second story was tried on top of this, the extracting-comb giving passage to the second set of wide frames. This worked well for getting lots of honey; but much of it was travel-stained. So you see these faults in the hive I was using led me to devise something better, which came in the shape of the Jumbo hive.

Now you may ask, "What is the Jumbo hive?" Just imagine you are here, and I will tell you the best I can. Now you are here. Let us play that an eight-frame hive is made of india-rubber. You take hold of one side and I the other, and pull; now pull hard; how much has it stretched? Only twenty inches. Pull again. Now we have it 22 inches. Now give it another awful jerk. There! now we have stretched it until it is 24 inches. That is wide enough for 16 frames and a thin division-board.

There, now let us get hold of the ends and give them a jerk. Hold on! you have pulled too hard. We want to pull them only just far enough so we can use a board $\frac{1}{2}$ inch thick and $9\frac{1}{2}$ inches wide for the brood-frames to rest, or $9\frac{1}{4}$ in. with metal rabbets nailed on. Let us get inside of it and take hold of the top edge of the boards which the frames rest on. Now let's pull away at this until we get it at least five inches above the top of the brood-frames. It is getting to be quite a good-sized hive, isn't it? When we commenced pulling, the entrance was in the end of the hive; we have not changed it, except to make it a little larger; but it is now in the side of the hive. We have also changed the L. frame to a crosswise one, without marring the frame in the least.

Let us sit down now and see what we have done. We have the length to the width, and what was the width to the length. But we don't want it india-rubber any longer, but good wide inch lumber, with the bottom nailed right on tight. Now lay a strip of $\frac{1}{4}$ -inch lumber right along on the ends of the frames for your section-holders to rest on; cover up your brood-frames with cloth or board, and you are ready for the bees. When the bees are ready for the sections, place six section-holders, holding four sections each, on the strip, over the center of the hive. Make the ends of your section-holders $\frac{3}{8}$ inch thick, and have tin separators nailed on each holder. You can make your section-holders with little legs on, so they can stand on the brood-frames and dispense with the sticks. I use them both ways, but can't tell which is the better.

When the bees have commenced nicely in these sections, move them to one side of the hive and finish covering the hive with sections.

When the bees have accepted this room, and are pulling the foundation in the last sections, take six of them and place on the other six. You will now have two tiers of sections in all stages of progress, on half of the hive. Now fill the other half with sections. You now have 96 $1\frac{1}{8}$ -inch sections on the hive, and have them away above the hive. Now make a rim of $\frac{3}{8}$ lumber, with a lath belt around, to set on the top of the hive. Better use ten-inch lumber, because, if the season is good, we shall need more room. When you come to add the third tier of sections you need take only one or two section-holders from the second tier that the

bees have commenced in, and put them in the third tier; then fill in with empty sections the second tier, where you removed these. You see you can build this hive up as high as you like, and add as much section room as is needed. Last season I built one up to the fifth tier of sections. I use flat metal covers for these hives, and set the hives tipping a little toward the front.

Now, what difficulties have I overcome? In the first place, I have done away with queen-excluding honey-boards by making the hives satisfactory to the bees. I have never had a queen enter the sections. I have no use for bee-escapes, as the bees are nearly all shaken off when the honey is removed from the hive. I can take the honey as soon as it is done—one section or a hundred as the case may be—before it becomes travel-stained. I have no warping of covers or shrinking of cases or supers to let the light in, so the honey is properly finished, and, consequently, a larger per cent of No. 1 or fancy honey is secured than by any other system I know of. Swarming is entirely overcome, if proper management is given to the brood-nest the early part of the season; but if they are let alone, packing left on top, they swarm earlier than those in eight-frame hives, as they are always stronger earlier in the spring—in fact, all the season.

Breckenridge, Mich., Apr. 19.

[The following is a private note sent along with the article. It contains a valuable point; viz., that a young lady is going to manage an apiary of Jumbo hives.]

Please ask questions, and I will answer them the best I can; but I labor under very many difficulties. I am nearly blind; have not been able to see to read or write for seven years, and am used up by that dreadful disease rheumatism. My eighteen-year-old daughter is doing this writing for me. She is to take charge of an out-yard of fifty or more Jumbo hives this season. You see, when they are once located the lifting is light; but I intend to use section-holders that will hold twelve $1\frac{1}{2}$ -inch sections on these, as I believe they have some advantage over those I have used. There are many valuable points I have not mentioned, but I think I have said enough—perhaps too much.

IN FAVOR OF LARGE HIVES.

“ONE-FOURTH MORE BEES,” “FIVE TO SIX FOURTHS MORE HONEY.”

By John Slabaugh.

Mr. Root:—I am not ready yet to send a post-al, telling you that I am tired of the discussion of an eight or ten frame brood-nest; but I am ready to send my experience. I can speak for my own locality only, my kind of honey, and my way of wintering bees. When the eight-frame brood-nest question came up first, I made

my hives the same as I had made them before—a ten-frame Langstroth, with a division-board to contract to eight or nine frames, as I used to. In case the eight-frame would not answer my purpose, I could take out the division-board and go back to the ten-frame brood-nest. After a four-years' trial, eight, nine, and ten frame brood-nest side by side fully convinced me that, for my locality, my way of wintering, and the kind of honey produced, the ten-frame is more profitable than either eight or nine. First, the less the brood-nest, the more inclined to swarm. There is, indisputably, more room for a big force of workers in a ten-frame than can be crowded into an eight-frame hive. It is said the two outside combs in the ten-frame hive are not filled with brood, nor is the old honey always used up by the colony. True, it is not always used up when spring comes. Those left-over stores are a safeguard in case of scarcity; and we all know that, if they are not all used up, there will be room in the brood-nest for a fourth more bees than in an eight-frame hive. I contend we can keep the bees with the one-fourth more bees just as long in the ten-frame hive, without swarming, as we can the bees with the one-fourth less in the eight-frame hive. The one-fourth more bees will give us from five to six fourths more honey.

It might be said this is theory and not fact. Well, I hived two swarms together the 23d of June, 1894, into a ten-frame hive. They filled the ten frames, and completed me 143 lbs. of section honey, while other ordinary swarms completed only about 56 sections. We want the biggest force of bees to gather the most honey. The eight-frame will not hold as large a force of bees as the ten-frame. If some of our colonies should seem to be rather too small for a ten-frame, why, use a division-board; that will be cheaper and much less trouble than one hive-body upon another.

My next point is for my locality. I use the double-walled hive, wintering my bees on their summer stands, not having to carry my ten-frame hives in and out of the cellar.

My third point is, I am running my apiary principally for comb honey, having the $1\frac{1}{2}$ -story and the two-story chaff hives with two supers.

As I make my own hives, I will make a twelve-frame one for trial this summer. If we here can keep bees from swarming, we can expect honey. Although this is not an extra good locality for honey, yet I have handled bees for from 25 to 30 years. I have never known bees here that would not always gather sufficient for winter stores, with the exception of some late swarms.

JOHN SLAUBAUGH.

Egton, W. Va., Mar. 15.

[Perhaps before you go too far in the matter of enlargement you had better consider carefully the following:—Ed.]

THE EIGHT-FRAME HIVE PREFERRED.

LOCALITY NOT A FACTOR IN THE MATTER; EXTRA-PROLIFIC QUEENS NOT NECESSARY; MORE BEES IN LARGE HIVES, BUT LESS HONEY, AND MORE BEES IN THE FALL AS CONSUMERS THAT HAVE TO BE FED; HOFFMAN FRAMES PREFERRED, AND WHY.

By C. Davenport.

As it seems some of the readers of GLEANINGS wish the discussion on large vs. small hives continued, perhaps you will allow me to say a few words on the subject. I prefer the eight-frame size; but I am a specialist—that is, I make a living, such as it is, by producing honey; and from quite a large and extensive experience I know I can make more money with a large number of frames in eight-frame hives than I can with the same number in ten or twelve frame hives. But in order to do so it is necessary to feed some seasons in order to keep brood-rearing up. I employ a man for each yard the entire season. These are cheap men; that is, one of them who has been with me for a number of seasons is a man who has one wooden leg; another is a man who is not able to do a hard day's work. But they can feed bees all right. I believe the majority of bee-keepers, though, keep bees as a side issue only, and many of these do not wish or have not time to do much feeding in the spring and early summer, if necessary. For this class, as a general thing, I think the ten-frame hive the best; for the honey those two extra combs will contain, will, in a poor season, enable brood-rearing to be kept up much better than it would be with only eight. If no feeding were done, and if a flow did come, the colony on ten frames would have a much larger force of workers to secure it; but when I have gone beyond ten frames, in general I have got just that much less surplus—that is, with a twelve-frame hive I do not get as much surplus within 14 or 16 lbs.; and, besides, such a hive costs more, and it is much harder work to handle them. I do not think the locality makes much difference to the specialist about the right size of hive. Of course, it might make a difference as to the time, and amount to be fed. I believe I can make more in any locality with frames in the eight-frame hive than I can with the same number of frames in larger ones; for my experience has been that, as a general thing, eight frames are enough for the best queens we can get at the present time. In saying "the best queens" I do not mean those that are the most prolific. I have had queens that would keep ten and in a few cases even twelve frames full of brood; but these queens needed to be prolific, for their bees were so short-lived that these colonies could not store as much surplus as others whose queens did not keep eight frames full.

Again, I have had very prolific queens whose bees lived long enough; but they were worthless so far as surplus honey was concerned, for

their entire time and attention seemed to be devoted to raising bees, and swarming.

Last season, a poor one in this locality, I had in the home yard a high-priced queen that I had bought the previous summer. She was in a ten-frame hive, and she needed ten frames, for she was very prolific. This colony did not swarm. They partly filled one super. There were perhaps 15 sections completed. An eight-frame hive stood right beside this one, the queen of which was a hybrid. I do not believe she laid an egg in either of the outside combs during the entire season; yet this colony filled 96 sections, and had plenty of stores for winter; and it is to-day one of the strongest colonies I have. Another colony, in an eight-frame hive, whose queen, a pure Italian, was also bought the previous summer, filled five supers of 24 sections each. There were a few in the last super that were not completed. They also had to be fed a little in the fall; but they are in good shape at this writing. This queen is hardly equal to eight frames; but I regard her as one of the most valuable ones that I ever owned.

Sometimes we see reports of queens that will keep twelve or even fourteen frames full of brood, and their bees store a large surplus. I have had two or three such queens; but they are very rare, and hard to get; and if we could get them, would they be any better? Suppose we had queens that would lay as much as two of the best ones we now have; could we get any more surplus for the same number of workers, or per frame, than we now do? I do not believe we could, from my experience. I believe that, after a colony gets to a certain strength—a strength with the right kind of queen—the eight-frame hive gives ample room to develop, and they will store as much or more for the same number of workers as one much larger; and I had much rather produce 200 lbs. of honey in two eight-frame hives than I would in one sixteen-frame hive.

Some of the advocates of large hives tell us that bees in such hives will raise a good many more bees during the latter part of the season, and thus have more bees for winter; and that, such being the case, they will winter better and build up faster in the spring. I will admit that colonies in large hives of twelve or fourteen frames will raise more bees at a time when there is nothing for them to do. This is why colonies in big hives do not store as much surplus. It takes a good deal of honey to raise and keep these extra bees over winter—enough so that, in large apiaries, it would amount to \$100 or more; and with me they generally die off in the spring before they have done much if any good. But I winter in cellars altogether. In outdoor wintering it may be quite different, and the same may be true of deep frames. I have better success in wintering with bees on the standard frames than I do on those that are deeper.

The past winter was, for certain reasons, very hard on bees in this locality, whether they were in cellars or outdoors; and at present some of the strongest colonies that I have are in eight-frame Dovetailed hives; and I have colonies in hives of many shapes, styles, and sizes—many more than I shall next year, if the present season proves a good one.

There has been considerable comment in the past year or two in regard to the best style of frame. I use and prefer the Hoffman. It is not perfect, by any means; but I have tried in a small way nearly every thing in the shape of a frame that has been offered in the last few years, and for the rapid handling of bees the Hoffman is ahead of any thing I have tried yet. Still, there are many who do not like them. In talking with a bee-keeper last winter he said he considered them a great nuisance, as it was so much work to dig the first one out. He was using the ten-frame hive, and there was no room in it for a follower-board. I do not use the Hoffman in ten-frame hives, but I can well understand that, without the extra space and follower-board, as there is in the eight-frame hive, they would be a nuisance. In my opinion the ten-frame hive should be made wider, and the extra space in the supers could be filled with a board. But you have made an improvement in narrowing the ends of the top-bars, and in having the metal rabbets project up behind the ends of them. Most of those I have, the frames are the same width at the ends, and the metal rabbets do not come up back of them, and I have more trouble with propolis being stuck on and between the ends of them and the hive than I do on the V'd edges; but the way you are making them will, I think, nearly if not quite overcome this; still, the way mine are, I can handle them much faster than I can loose hanging frames, or frames that are hung on metal rabbets and spacers combined; for with the latter we have not the lateral motion so necessary for the rapid handling of frames. The former have it, but you can not use it with two or more frames combined, as you can the Hoffman, on account of smashing bees, and occasionally a queen also.

Southern, Minn., May 6.

[This I consider to be one of the strongest and best articles we have ever received, and I think most of our readers, after perusing this carefully, will be convinced that the eight-frame hive is and should be kept the standard. Mr. Davenport is a very large and extensive bee-keeper, and his statements can be taken as in some degree authoritative.

Regarding the Hoffman frames, I might say that the article on that subject in the editorials was written before the above came to hand. But it can be seen how nearly Mr. Davenport agrees with what I have said regarding the rapidity with which Hoffman frames may be handled. It is indeed true, that, to handle such frames properly, it is necessary to have a removable follower-board. The ten-frame hive ought to have been a little wider; but as it was standard in width as we send it out, we could

not very well change it; and we did not at the time, and do not now, think that such size of hive will ever be universally adopted.

I believe we have the Hoffman frame down now where it will not have to be changed or improved. The narrowing-up of the ends, while it facilitates the handling of the frames themselves, does away with a great deal of the propolis attachment at the ends. I find that, as friend Davenport says, the Hoffmans are held more by propolis attachments at the ends than by the uprights along the V edges; but having narrowed up this end, that sticking propensity is reduced to a minimum.

It is true, the Hoffman frames are not perfect, but neither is any other good thing perfect; but I believe it comes the nearest to filling the bill for a general all-around brood-frame; and the great beauty of it is, it is everybody's property. All can make and use it.—E.D.]

HOW THE BEES WINTERED AT DR. MILLER'S.

THE NECESSITY OF A BEE-FLIGHT BEFORE PUTTING INTO THE CELLAR.

By Emma Wilson.

Last fall the exceedingly good weather during the month of October fooled us into leaving our bees at the out-apiaries so long that we were caught napping at last. The weather suddenly turned very cold, and the bees did not have an opportunity for a good fly before they were put into the cellar. October 31st the first two loads from the Wilson apiary were brought home. Nov. 1st all were brought home from the Hastings apiary. Nov. 2d being a warm day, all these bees had a tolerably good fly. The last two loads of bees were brought home from the Wilson apiary Nov. 3d. Nov. 5th these last bees were flying, with the thermometer at 40°, while the other bees remained quiet in their hives. Nov. 20th the bees were put into the cellar. They had been through two very hard freezes, with the thermometer at 7 to 10° above zero, with 2½ inches of snow on the ground. We disliked putting them into the cellar without a good fly, but did not dare to leave them out any longer. If we could have foreseen the future it would have been better to leave them out until Dec. 21st, as that was a nice warm day. And it would have paid us well if we had carried them out for a fly on that day and then carried them back again.

About Jan. 10th the house cellar commenced to smell bad, and two of the strongest colonies were pretty badly daubed.

March 18th was a nice day; and as many of the colonies were in such bad condition we concluded to take them out for a fly, even if we had to carry them all back again. There were 110 colonies put into the house cellar. Of these, 94 came out alive and 16 were dead, and 21 more colonies have died since taking out. The house cellar contained the Wilson and Hastings bees. All of the Hastings bees came out alive, and 100 per cent of them are alive at the time of writing. Those that died from the Wilson apiary,

as nearly as we can make out, were all from the two loads that were hauled last. In the Wilson apiary the colonies were much heavier and stronger than either of the others, it being the one apiary that required little feeding for winter. Now, what caused the mortality? It seems a very plain case that it was the failure to have a good fly after being hauled, for that was the only difference between those two loads of bees and the rest, as they were wintered in the same cellar under exactly the same conditions. I guess we won't be caught napping again. No bees of ours will be likely to be hauled as late as November hereafter.

April 4th we carried the bees out of the shop cellar. They belong to the home apiary. They were in fine condition when taken out, and to all appearances could have remained some time longer in the cellar, without injury. Of the 89 colonies put into the cellar, two died.

Marengo, Ill.

[I take it that your bees wintered perfectly, with the exception noted. I should not have supposed that the lack of a good flight just after being hauled home, and before putting them into the cellar, would have made all this difference.—ED.]

CALIFORNIA ECHOES.

By Rambler.

Many standard appliances used in the East are in but little use here. The bee-tent is a valuable adjunct to the apiary, but we seldom find one in California.

Messrs. Gemmel and Alpaugh,* of Canada, made a host of friends while here. We should like to annex them to California. It would lengthen their days of usefulness, and give us two more live bee-keepers.

In the last *A. B. J.*, Mr. Dadant thinks the new forage-plant, sacaline, is a honey-producing plant. If it proves true, it means much for California, for just now there is much talk about introducing it into Southern California; and if New Mexico can grow sainfoin, California surely can. Every bee-keeper who has a spot of ground upon which to test these plants should sow the seeds this year.

The Hon. J. M. Hambaugh, of Illinois, sojourned for several weeks in California; and in summing up his observations in a recent issue of the *American Bee Journal* he said, "The half has never been told." When you consider that several persons have attempted to throw doubt upon the statements of such writers as Prof. Cook, Dr. Gallup, and the Rambler, the above from Bro. Hambaugh is truly helpful. We have said much about California; but, remember "the half has never been told."

There is much said recently in the *American Bee Journal* about the practice of spreading brood in the spring, the majority taking ground against it. It is very safe advice when

applied to the bee-keeper in the cold corners of the East; but here in California the spreading of brood can be indulged in with but little danger to the colony, and it is largely practiced here in the spring. It is safe to say that all of the leading bee-keepers do thus enlarge the brood-nest, and equalize until the honey-harvest commences. It pays in dollars.

Please allow me to return thanks to the "Ladye Faire" who sent me that "confusion" of poetry. I am looking with much favor upon the fair sex just now, and am poetically disposed; and, being a lonely bachelor, I have been in a deep study over the following for some time:

"Fact is," said the one bee-man, "I married because I was lonely as much as for any other reason. To put it tersely, I married for sympathy."

"Well," said the other bee-man, "you have mine."

Eastern people come to California for various reasons—some for their health, some to engage in fruit culture, some to produce honey, and some to fill in the various other industries. Nearly all of these classes do well. They very sensibly consider that this is a new country, and it requires time for development, and they will endure a little hardship at first, in order to reap the advantages later; and, speaking of bee-keepers, there are hundreds of them who have made money out of the business, and thousands more will do the same.

There is a class of people, however, who arrive here from the East, expecting that every breeze is balmy, every sunbeam evenly balanced between heat and cold, and that golden nuggets are found in every sandhill. Owing to the fact that we do have disagreeable climatic features, and sometimes a failure in crops, precious little loose gold, and now and then a real bad real-estate man, this class of enlarged expectancy soon shake the dust of California from their feet, and seek the East, howling their grievances to high Heaven. We look around us and expect to see the whole of the State sink; but, no; she still waves; and the evidences of prosperity—growing towns, thriving communities—lead us to look with pity and a derisive smile upon the rantings of the mistaken emigrants.

Moral.—If you are doing well where you are, are respected, healthy, and passably contented, by all means stay there. If you have poor health, and \$1000 or more to invest you will do well to come to California. If you are along in years, remember what Dr. Gallup says: "California is the old man's paradise." My advice at all times is, to look well before you leap.

Mr. Gee and myself find the progeny of the queens we got first from you to be far better honey-gatherers than the other bees we have had. Mr. Gee has four strains (New South Wales bred), but he gives the palm to yours, both last year and this.

Minto, N. S. W., Aus., Dec. 24, 1894. P. D. PAGE.

WAX.

THE QUALITIES AND SOURCE OF WAX.

By Karl Rudolph Mathey.

Beeswax is a substance which is produced the world over by the various members of the *Api-dæ* (bee) family. Opinions vary greatly as to whether bees obtain it from the different kinds of sap which they find on certain flowers which serve them as food, or whether the pollen of such plants furnishes the requisite material. Wax itself may be considered either as a secretion or as a separate product; for when bees are quiet in their hives the wax may be seen in the form of minute scales, exuding from between the little rings of their abdomen. The worker bees either take these scales up from the bottom of the hive or else they receive them directly from the bees and form cells therewith.

Many bees are kept in European countries—Austria, Germany, France, Russia, Spain, Italy, and Turkey; and these countries furnish the main part of European beeswax. And, too, the Orient, especially Persia and Asiatic Turkey, furnishes considerable amounts, to which may be added the yield from the East Indies, Japan, China, Africa, and America, though not all the wax from these countries is designed for European consumption. German wax comes from North Germany, from the heathy regions of the lower Elbe, from Hanover, Holstein, East Friesland, etc. In Middle Germany it is more particularly from Thuringia (a part of Saxony) that much good wax is produced; Bavaria, especially Mittle Franken; then Wurtemberg and Baden have, by careful bee culture, produced a superior wax. German wax forms no article of commerce, as it is used mostly in home consumption. Austrian wax, Bohemian, Moravian, Silesian, and that from Bukovina and Poland, are ranked as among the best kinds. The wax of Bohemia, Moravia, Silesia, and Galicia, is among the softest. Recently two kinds have been noted—the West Galician, having a strong odor of fir-tree rosin, and that from East Galicia (Bukovina), varying in color from red to brownish-yellow. It has a fine odor and considerable firmness. As buckwheat is a prominent plant for bee-pasturage in these regions, the wax produced therein is of the best, as is the case in all districts where this cereal is grown in sufficient quantities.

Hungary and its surrounding country produce much wax; also the region around Fünfkirchen, and especially Banat, with its rich fields. Siebenbergen sends much wax to the Buda-Pest market, and finds there in all cases willing buyers. Illyria (Carniola) and the Tyrol, and the country around Klagenfurt, furnish wax at all times, against which the Russian wax offers no competition, on account of the unsightly shape in which the latter comes. The best kind of wax known is the Bosnian—even better than

the Turkish. But it is the dearest, and the reddest in color.

All countries which use much sweet (and that is especially the case with Turkey) make much use of honey, and pursue bee-keeping with particular zeal and scrupulous care, and hence are in condition to offer to the world a wax of surpassing excellence in quality. Almost equal to the Turkish wax is that from Greece, whether it be from the mainland or from the numerous islands of that country. The French follow bee-keeping with the greatest assiduity. Brittany and southern France furnish the best wax. Burgundy, Landes, Normandy, and the regions around Bordeaux, produce inferior kinds of wax; but it does not appear on the market, as it is all used at home, and considerable quantities are even imported. In Paris there are several large firms that deal in honey and wax exclusively; and large wax-bleaching establishments, with hundreds of workmen, are engaged in this business. Spanish wax, in blocks weighing two or three pounds, is but little sought after in comparison with the French. Apiculture in Spain is in a rather primitive condition. Italy produces, in Sardinia, Lombardy, and Venice, considerable quantities of wax, and exports some, notwithstanding the great amounts used at home.

Wax, as produced by the bees and worked into comb, is snow-white; but that which comes from the hive, separated from the honey, has, on the other hand, a yellowish cast, varying in intensity. It is generally furnished in level cellular honey-combs by bee-men, from white to dark yellow, or now and then even a grayish yellow. It has a granular and generally shelly appearance where broken, showing a crystalline structure. At a low temperature it is brittle; but the warmth of the hand renders it soft and yielding, in which condition it can be kneaded. It has a slightly spicy taste, and does not stick to the teeth when chewed. In water or cold spirits it is not soluble; but in boiling alcohol it dissolves readily. On cooling, however, most of it returns to its original condition, so but little of it remains in solution. Sulphuric acid, ether, benzine, and spirits of turpentine, as well as most of the etheric oils, dissolve it completely. It admits of combination with most fats and fatty oils, in all proportions, by melting.

The specific gravity of pure beeswax is from .965 to .972. Its melting-point lies between 143 and 145°, and it becomes hard again at about 136°. If a higher temperature be applied, the wax is entirely decomposed, and vaporizes, but leaves no perceptible acrolin odor.

The coloring-matter in wax bleaches best in full sunlight. Bleached wax is found on the market in round, thin, translucent sheets. It has a mildly rancid smell, no taste, and melts between 147 and 152°, having a specific gravity ranging from .970 to .976, but preserves in other respects the original properties of yellow wax.

RAMBLE 132.

BEE-KEEPING IN LAKEPORT.

By Rambler.

When we pulled out again from our camp the added factors to our cavalcade attracted much attention. The people who were lounging around the springs cast curious glances at us as we rolled out of sight through the dust. Susan B. formed a cordial attachment to our ponies; and whenever we would get beyond her vision her shrill neighing reverberated up the mountain sides. No, Susan B. was not wind-broken, even if she was old and some of her teeth loose.

We traverse Cobb's Valley, and meet many new features on the way. This valley seems to have several fine ranches which were evidently a sufficient support, without living off the tourist; but we discovered that the tourist was the legitimate prey of even the ranchers. Here in the pretty shady Glenwood we had to pay 20 cents per loaf for bread. The postmistress of the nook was real pretty and sociable, and was fully as well posted in relation to roads and distances as the village blacksmith; and while she sold us stamps and bread she gave us much valuable information. Bro. Pryal wanted to camp right there and then, at midday. Wilder and I would not listen to such a proposition, and, cracking the whip, swung around the corner out of sight. Of course, Susan B. whinnied, pawed the earth, and whirled around; the postmistress stopped in the middle of a story, and fled to her little office. Susan B. pulled so hard on the bits that Pryal had to let 'er go. This little inkling of our friend's admiration of the fair sex gave us some fears that there would be disastrous results in the future, which, alas! did prove true.

Cobb's Valley was also noted for its delightful camping-grounds, running streams, and shady nooks. At the northern extremity a mountain 4000 feet in height, named Uncle Sam, beamed down upon us. Geologists tell us that Uncle Sam bears the proud distinction of being an extinct volcano. The evidences of volcanic action were visible in the rocks; for here was a whole mountain, not far from Uncle Sam, that appeared to be constructed wholly of black glass.

Our friend the blacksmith again gave us much valuable information. This blacksmith's impressions of California were peculiar. Southern California, he said, lived off the eastern tourist; said tourists are naturally stingy, and spend but little money; consequently the south end of the State is not prosperous. Northern California, on the other hand, depended upon the San Francisco and Oakland tourist, and they spent their money with reckless freedom; therefore this portion of California was the more prosperous. The people and the towns, however, belied his statements, for the song of

hard times was loud and long; and now and then a town was in the fatal stages of dilapidation. In Kelseyville were numerous vacant houses with broken doors, paneless windows, and shutters awry. Near this town we met a tourist leaving the country, and he held a very pronounced opinion in relation to the Swiss features, characterizing them as a delusion and a snare.

Hurrah! here is Lakeport, and this time the lake. Clear Lake is 28 miles in length, and 10 wide. Upon its shore we pitched our camp, tired and dusty. Several of those little gasoline-launches were puffing to and fro across the lake, giving quite a lively appearance to its placid surface.

Lakeport is quite a pretty town, with a fine climate. The lake seems to be naturally adapted to the breeding of billions of buffalo-gnats. In the evening, clouds of them surrounded our lantern and persisted upon going to roost in our tent; and in the town the space between windows and the screens was several inches deep

BITES

with dead gnats. The nuisance was, however, only during the evening. In the morning they retired to the tules that lined the shore. And what a beautiful picture our lake presented at sunrise! The air was filled with smoke from forest fires further north; and the sun, as it arose, appeared like a great red ball of fire. The lake, as smooth as a mirror, reflected the sun in a long blood-red pathway across the lake. The moon and its silvery pathway we had witnessed many times upon our lovely eastern lakes, and it has been likened unto angel-walks from earth to heaven; but this blood-red road suggested the pathway of demons from earth to some unknown sphere.

Before entering Lakeport, Mr. Pryal informed us that there must be a progressive bee-keeper in or near town, for one P. J. Moreley had purchased queens from him. Mr. Pryal took a turn into town after we had camped, and found his man. Mr. Moreley was the lead-

ing (and I am not sure but he was the only) harness-maker in town, and bee-keeping he conducted as a side issue.

Mr. M. came from that good but cold country, Sweden, and had been a resident of this country for only five years. He occupied a very pretty residence in the edge of the town, surrounded by trees and luxuriant foliage, and the bees were in neat dovetailed hives placed here and there under the trees; and, though some of the hives were only a few feet from the street, the bees were not troublesome to the neighbors. Mr. M. seems to be a thorough mechanic, and showed us a new kink in putting together the dovetailed hive. A piece of tin bent at right angles, long enough and wide enough to cover the ends of the dovetails, is securely nailed to the corners of the hive. There was no chance for sun and rain to get in their warping effects.

Upon the date of our visit, Aug. 30, the bees were working quite lively, and we were shown quite a number of sections in which the bees were storing a good quality of amber honey. We were also shown combs nicely drawn from foundation, and well filled with honey, which had been inserted in the hive on the 26th, or Sunday, five days previous to our examination.

When Mr. Morley first came to this country he used a hive that was in general use in Sweden. This hive was 18 inches deep, and contained 24 frames. The latter were 14 inches deep and 10 inches in length. From one of these hives he secured 900 lbs. of honey. Having no extractor he cut out the combs containing honey, on Sunday. By the next Sunday

flower, and was of a bad quality. Mr. M. finds a home market for his honey, selling his comb honey for 25 cts. per lb., and the extracted for 10 cts. Mr. Pryal was pleased to be introduced to a queen of his own breeding, and showing finely marked progeny. We were also introduced to some Carniolan stock from Mrs. Benton, and a strain of Italians from Lockhart's apiaries. Mr. Moreley had bred the Carniolans in Sweden, and had much experience with both races; and it was his opinion that, for business, the Italians were far superior to the Carniolans.

Mr. M.'s smoker was of that kind which causes some controversy and any amount of ugly comment. It has been described as follows:

"A little roll of tobacco-leaves with a fire at one end and a sucker at the other," or the cigar. Mr. M. had a polite way of wafting the smoke over the bees. They understood the plan, and were handled without gloves or veil.

Mr. Moreley would be a successful apiarist upon a larger scale; but the transforming of leather into horse-trappings seems to have the greater attraction, and in that business he seems to be successful.

Lakeport is some distance from railroad transportation; and this, with the dark grade of honey usually obtained, would probably deter the apiarist from making honey a specialty in this location.

Mr. M. kept abreast of the times by being a subscriber to GLEANINGS and the *Review*; and we had a very enjoyable visit with him.

We stopped a day in Lakeport, in order to allow Mr. Pryal's propensity to fish to have full play. His efforts piscatorial resulted in about as many bites as Wilder's signs of deer. I was pleased that my traveling-companions mounted such opposite hobbies; for when they did both mount the same hobby later on, ruin and devastation marked their pathway.

THE T SUPER, AND WHY THERE IS NOT A DEMAND FOR IT.

WHY SOME THINGS GO AND OTHERS NOT.

[I would explain to our readers that A. B. Anthony has made some suggestions regarding the T supers; but as Dr. C. C. Miller has had more experience along that line I forwarded them to him for reply. The doctor sent his reply to me, and I have in return again sent them on to friend Anthony. I have not space to give the whole of the discussion, but I give the "tail end" of it. Dr. Miller's comment on a previous letter of Mr. Anthony's appears first.]

If I understand Mr. Anthony correctly, he proposes to change the length of the brood-frame so as to accommodate more perfectly the super. Then he will have a super $\frac{3}{4}$ inch longer inside than four sections, and fill up that space with wedges at each end, or with a wedge and follower at one end. In actual practice I find no great difficulty in having a super shorter inside than the brood-chamber. He can tell

MORELEY'S SMOKER.

the bees had built new comb and filled it with honey; and the cutting-out process was performed again. The operation was continued through the entire season, with the above results. The honey was gathered from wild sun-

better after trying how he will like the proposed change, but I'm not sure there will be any real gain. If I am not mistaken, the main thing he is after is to have the sections crowded close together end to end, so there shall be no space between them. That, of course, is to avoid the crack for bee-glue. Now, there can be no advantage in that over the plan of having the little top separators crowded between the sections; for what difference can it make to a section whether it is crowded tight against another section or against another piece of wood? But it may be more satisfactory to him to put the matter to actual test.

At A is shown the close fit between two sections, and at B the top separator between. If they are crowded equally tight together, what chance is there for bee-glue in one case more than another?

C. C. MILLER.

Marengo, Ill.

[The following is the reply by Mr. Anthony. The experience that I have had personally with T supers inclines me to agree with Dr. M. rather than with Mr. A.]

Mr. Root:—Really I think the doctor must have been sleepy when he replied to the last article of mine. I did not mean we should change the length of the L. frame to accommodate the super. I only said, "Let us suppose our frame is 17 inches long." I did that hoping that E. R. Root would notice it as one point in favor of a shorter frame, as he had somewhat expressed himself as wanting to hear from me on the subject of hives, and because my own brood-frame is just that long.

I think if any one would try to find the cause for the $4\frac{1}{2} \times 4\frac{1}{2}$ section coming so largely into use, the first and principal reason would be on account of the length of the L. frame. The doctor says there can be no advantage over having little top separators between sections, and that there would be no difference between a section crowded against a section, or one section against another piece of wood. He forgot that we were making the super suitable for open-side as well as closed sections. Separator stuff closed the opening along the top of sections; but with the open-side sections there will be all that space under the separator stuff and over the T tins to be filled with propolis.

Mr. Root thinks that the T super is so little used now that the subject might as well be dropped. I am sorry that he thinks so. Almost all living kind seems to have its leader or authority to look to, and it is right. It is in E. R. Root's hands that most of the responsibility lies as to what shall be adopted by the beekeepers of the United States. But very few people are capable of making the wisest choice as to what is best for them to use; and some of

the few who are, prefer to use what the rest do, so as to be in good company. It only wants Mr. Root's sanction, and in three years it will be all the go. If Mr. Root would only give the matter a little close attention, and call others' attention to it, I think they would realize the value of its simplicity, its cheapness, and adaptability to the different widths of sections that people want.

If formed as I have advocated, I am sure they could put in and take out sections quicker and easier than in other supers of this day. The one great necessity is to have one and the same thing fill the wants of all. I have seen the time when I was out of sections, and could have bought of a neighbor bee-keeper; but his width of sections would not fit my supers. Also the time when I could have accommodated my neighbors had it not been for the same difficulty.

Looking around us at other things, we see that the wheels of all vehicles run in the same rut; all locomotives on the same track; all axes fit the same handle; all kettles fit the different stoves; plows turn the same furrow, and machine after machine goes the same round in the field. Progress must have its way; and to look in the same line down to this very year we find the Columbia bicycle folks coming out with a pump-and-valve attachment that fits other wheels and what is coming to be the standard. And so should bee-fixtures have the same combined fitness that is found in other things in these more modern days.

A. B. ANTHONY.

Coleta, Ill., April 17.

[Now, friend A., you intimate that whatever I push will surely "go." I plead guilty to having started the use of some new implements; but these are implements of real merit. I have tried to push some other things that did not go that I thought had real merit. I think the Pratt automatic hiver, for instance, under certain circumstances, might prove a valuable assistant in the apiary, and it did indeed do well for us. I pushed it in the catalog and in the journal; but it did not go at all. And, again, inasmuch as yourself, Dr. Miller, and some others, think the T super should not be crowded out of sight, we have put in our catalog a better illustration, and improved it so it can be used on the Dovetailed hive, and yet take $4\frac{1}{4}$ sections. Here is the cut.

By cleating the ends, shorter frames are unnecessary; so also are handholes. Well, although we have given it more prominence, and improved it so that it leaves nothing to be de-

sired, it doesn't go, and I doubt if it would were we to say it was "just as good."—Ed.]

COMBINATION QUEEN-AND-DRONE TRAP AND SWARM-CATCHER.

By Henry Alley.

There is a demand by a large number of beekeepers for a simple, practical, and cheap device for either hiving or catching a swarm of bees when it issues. A practical self-hiving arrangement has not as yet been devised, as experiments the past few years have demonstrated. I think the device here described, for catching a swarm of bees, will prove not only practical, but will prove satisfactory to all who try them. The arrangement is simple in construction, inexpensive, and, though not a self-hiver—that is, the bees are not hived in the

hive they are to occupy as a permanent home—yet the swarm is caught and hived till they can be placed in a hive or otherwise disposed of as the apiarist desires.

The swarm-catcher is used in connection with the Alley queen-and-drone trap, and can be used on almost any style of hive, and fastened thereto with little or no trouble. Some of the advantages of this device are, that the apiarist can go from home one or more days at a time, and rest assured that, should his bees swarm during his absence, they can not decamp, and they surely would be found in the catcher—a fact one can know by a mere glance at the catcher and without an extended examination

either. In case a swarm is found in the catcher, it will require not over one minute's time to transfer the bees to a hive.

Although the catcher is used in connection with the queen-trap, the trap will not have to be altered in the least to connect it with the catcher. When the catcher is not needed for catching swarms it can be removed, while the trap can remain in position to trap drones or a queen as the case may be.

This arrangement in no way interferes with the bees while they are at work, and would hardly be noticed by them, even when first put on the hive.

This arrangement can be used as a self-hiver if any one so desires. All that is needed is to place a hive of combs over the catcher, as seen in the cut, or frames having starters in them, connecting the catcher and hive by an opening direct up through the top of the catcher and bottom of hive. In my opinion this arrangement would come nearer a practical hiver than any device yet described in the various bee-publications.

And now, friend Root, one word about the improved queen-and-drone trap. Those who have not used the improved trap know but little about what a perfect queen-trap is. Unlike the old-style trap, the new one has metal in the back side as well as on the front. The bees while at work can pass in or out through any part of the trap. There is no such thing as killing bees by being caught in the trap. Unless care was taken in placing the old-style trap on the hive, a colony of bees would be smothered. Not so with the new style, as there is no way the entrance to the hive can be closed by the trap, and the bees can pass up the back side of the trap, and pass out or in. The trap as now arranged does not prevent free ventilation of the hive during the hottest weather. But in some cases where there were very large colonies the old-style trap did not admit of sufficient ventilation.

Wenham, Mass.

[Perhaps the readers will understand the swarm-catcher a little better when I say that the device is simply an ordinary Alley trap, the upper compartment of which has been enlarged to take a large swarm, and hold it for a day or two till the apiarist can give it his special attention. The hive on top, with the Alley trap, as shown in the cut, is not necessary when the device below is used simply as a *swarm-catcher*, but only when used as a *self-hiver*. I have no doubt the arrangement will work as Mr. Alley says.—Ed.]

GOLDEN'S BEE-FEEDER.

By J. A. Golden.

Mr. Root:—Having shipped you one of my combined hive-covers and bee-feeding arrangements, specially named bee-feeder, permit me to give you a short description of the device and

its advantages over any other, so far as my experience goes. In doing this I do not wish to be understood as having any new-fangled dish or pan to hold the syrup, more than any open-top vessel.

The special features of my invention, then, are, first, a brood-frame cover provided with a bee-space over the top of the brood-frames, permitting the heat from each cluster to unite, as from one compact cluster, during cold weather; also, bees are not required to travel to the bottom or around the extreme ends of combs, to pass from one comb to another to feed; and as this cover is made of thin lumber, it admits of ample ventilation; thus sweat and moldy combs are overcome, which undoubtedly create disease, which so frequently occurs when oilcloth and other substances are placed in contact upon the frames.

Second, the cover is provided with a receptacle or box made permanently open, the cover having a wire-screen cover fastened by two small hinges. Upon the board, near one end, inside of this box, a slot $\frac{3}{8}$ x 6 inches is cut, permitting the bees to step from the brood-frames right into the receptacle, in which any open-top feeding-utensil is placed, and is always ready to receive feed, either for stimulating brood-rearing, cell-building, winter stores, or filling out unfinished sections at the close of the honey-flow, thus doing away with gathering up feeders, smoking the bees, lifting lids, pulling off oilcloths, exciting bees, often subjecting the young tender brood to a blast of cold air, the latter being detrimental, as every rational bee-keeper knows, and the tired apiarist is relieved from the arduous work required in the above, besides frequently preventing unwelcome visits from robber-bees.

I wish to say, before closing, that, when feeding extracted honey back to finish sections at the close of the honey-flow, have a bee-entrance at each end of the feed-receptacle box, and place a feed-dish between. Thus the bees will do the work in a shorter time, having ample

and shorter space to travel; and I also find, by thinning the honey somewhat, the bees can perform the work in a much shorter time; and after supers have been taken off, the covers are replaced upon the hives, and there remain.

Reinersville, O.

DRONES AND SWARMING.

Question.—I am told that bees never swarm unless there are drones in the hive. Now, will it keep my bees from swarming if drones and drone comb are kept out of the hive?

Answer.—There are a few bee-keepers who argue that, if all drones and drone comb are kept out of the hive it would be, to some extent, a preventive of swarming; but with me I have failed to see that this matter of drones has had any thing to do with the matter of swarming whatever; for I have several times had hybrid colonies in my apiary, from which I have taken all drone combs, and not allowed them to rear drones, because I did not want my young queens to meet such drones; yet, so far as I could see, these colonies swarmed as promptly as did those having drones. I said, "from which I have taken all drone comb," and meant just this; but will explain that, to keep all drones out of a hive, means the opening of that hive every 20 days, and decapitating a few hundred drones in their cells; for where all drone comb is removed, drone-cells will be built in all sorts of out-of-the-way places, for I have yet to see the hive containing a populous colony during June and July that had not a few cells of drone comb in it; and I do not believe that these few cells can be kept out; for worker comb will be cut down and drone built in its place if a few cells can not be gotten otherwise. From my experience in the past I would say that it is not practical to try to keep all drone comb out of any hive, but, rather, have just one frame in each and every hive, having from six to twelve square inches of drone comb in it, and have such comb stand in a certain place in each hive, so that the apiarist may know just where it is; then every twenty days open the hives from which it is desired that no drones shall fly, and decapitate them, thus making a sure thing of the matter, and fully satisfying the bees. In this way you will not have a few drone-cells scattered all through the hive, nor will you have to use a drone-trap at the entrance to catch undesirable drones. If this comb with drone-cells is placed near the outside of the hive, and the drone comb is near the top-bar of the frame, you will not have to decapitate the drones more than three times during the season, for the queen will be slow in

depositing eggs in it; and when honey comes in, the bees will fill it with honey, thus keeping the queen from depositing eggs in it.

SULPHURING HONEY.

Question.—I see by GLEANINGS for April 15th that some have trouble in sulphuring honey on account of turning the combs and wood of the sections a yellowish green. How do you prevent this?

Answer.—This is one of the nice points, and one on which I did a good deal of experimenting in the past, after nearly ruining the first lot of comb honey I tried to sulphur; for at that time no one had given any caution regarding this matter. Honey should be stored in a small room where the temperature can be kept high, so that it can ripen out after the sections are taken from the hive. The sections should be stored on scantling, placed in such a way that the fumes from burning sulphur can pass between the sections all through the whole pile, if signs of the larvæ of the wax-moth are found. The right quantity to burn to kill the larvæ I found to be, after many trials, three-fourths of a pound to every 200 cubic feet contained in the room. Put some ashes in an iron kettle, and on the ashes a few live coals; pour the sulphur on, shove under the pile of honey, and close the door. Now leave for about fifteen minutes, when the door should be opened and the smoke let out. If too much is used, or the room left closed too long, we are sure to have the sections and combs discolored. Really the best plan is to have a window in this honey-room, so that, when the door is shut, you can go to this window and watch the flies, which will collect on it as soon as the fumes from the burning sulphur begin to fill the room. One by one they will begin to be stupefied, and in from eight to twelve minutes the last one will have ceased to move. I used to wait two minutes after the last fly was lifeless, then open the door and window, so as to cause a draft and let the smoke out quick, and after thus working I never failed to kill the wax-moth larva, nor did I ever have any combs or sections colored. That you may not take in the fumes of sulphur yourself, the window should be made so it can be opened from the outside as well as the door. Some seem to think that a red-hot iron dropped in the sulphur gives better results than pouring the sulphur on the coals, as given above; but with me the coals do good work, and are always handy from the cook-stove, as we burn wood in the summer season.

"WHAT SHALL WE DO?"

Question.—Did you read what A. I. R. said under the above heading on page 328 of April 15th GLEANINGS? If so, is such doctrine sound?

Answer.—I do not know that the GLEANINGS friends will allow an answer to this question in this department; but as I believe that Bro. A. I. Root will sanction the "greatest good to the

greatest number," I will venture a few words. The "good Book" says, "If any will not work, neither should he eat," which coincides with Bro. Root's "God surely helps those who help themselves." Then Bro. R. is quite right in saying that "the world owes no man any thing until he has earned it;" but when he comes to advise us not to have any thing to do with bankers, manufacturers, etc., who show themselves greedy and dishonest, I fear he did not stop to fully take in our present situation. His father succeeded in doing what he tells us of "without any help from millionaires," because there were no millionaires in this country at that time; for, prior to 1860, there was scarcely a millionaire in this country, and the legislation of this country at that time gave that father the privilege of keeping fully 95 cents out of every dollar of wealth which he produced from the land covered with woods which he occupied, to use for himself and his loved ones, while the wealth-producers of to-day in this country have to part with 52 cents out of every dollar's worth of wealth they produce, to add to the millions of the few who force up prices by combines, trusts, corners, etc., of the necessities of life, that they may amass fortunes that no man can comprehend, out of the toil, sweat, and deprivations of the masses. Fifty-six of the actual necessities of life are controlled and cornered by trusts and monopolies; and yet Bro. Root says, "have nothing to do with them." Abstain from beef, and punish the dressed-beef combine; abstain from bread, and punish the millers' trust; from light, and punish the oil combine; from coal, and punish the coal combine. Is it possible to have nothing to do with these? According to the *Chicago Tribune*, the Standard Oil Co. cleared fully \$75,000,000 in ten days by the recent forcing-up of prices on oil, with not a farthing greater cost of production than before. The coal barons have lately met, and decided that the output of coal should be lessened, and the price advanced 50 cents per ton. The dressed-beef trust have doubled the prices of beef to the consumers in our eastern cities, while the producer of said beef, and the retailer, have to be content with nearly the same pay for the wealth produced by them as before. I can not think Bro. Root fully realized the import of what he wrote when he penned those sentences. "Turn the light a little lower, John, so we shall not burn so much oil, for oil has gone up in price, you know, and all we have to sell brings less. Use as little coal in building the morning fire as possible, John, for now it takes 50 lbs. of honey to buy a ton of coal, while in 1874 it took only 14. Let us economize all we can, for at best I almost fear we shall not be able to meet the rent this year." Such was the conversation heard at a bee-keeper's house one evening not long ago; and it only represents the condition of multitudes of hard-working people strug-

gling for an existence, while the few revel in wealth at their ease, said wealth being wrung from the masses by the legislation of the past. Did God ever intend that a few men, through unjust legislation, should enjoy the good things of this world while the many should suffer? Is it not about time we began to legislate for the masses instead of the classes?

[Friend D., I most heartily agree with the text you quote—"If any will not work, neither shall he eat." But you surely do not mean that every man must necessarily earn his bread entirely by muscular work. Quite a few of the readers of GLEANINGS buy potatoes in the fall, and hold them over till the spring, taking great pains to keep them in good condition in the hope of getting better prices. Now, whether they buy the potatoes in the fall, or raise them on their own farms, they are to a certain extent speculating on the chances of a scarcity in the spring. Whoever furnishes potatoes for seed must be more or less of a speculator; but may not his work be as honest as that of his neighbor who sells his potatoes as soon as they are dug? If the Standard Oil Co. did clear 75 millions of dollars, as you say, in ten days, it was a gigantic gambling operation; and the gambling mania of the present time is one of the most terrible evils that threaten us. You say my father kept 95 cts. out of every dollar, but that we to-day can keep only 52 cts. out of every dollar, etc. I believe I have read enough in regard to the matter you allude to, to understand it pretty well; and if I am correct there are only comparatively few people who agree with your statement. You suggest that the times are terribly hard for poor people. Suppose I should take the time and space to make out a list of the things that are cheaper for poor people than ever before. We should all consider that, when any thing gets to be very cheap, it is bad for the producer, but a blessing to those who have to buy. The farmer gets but a small price for his wheat. At least one consequence is, that every humble home can have bread cheaper than ever before. I would not abstain from beef; but I would buy it from my nearest neighbor who has beef to sell, and so with bread. If the miller is greedy and dishonest, I would have a little mill of my own. I have found these little mills in many homes during my travels; and they have proved to be a great economy and comfort. I never found any better bread, to my notion, than that made from home-made flour. There are men who produce both coal and oil who are not in any combine, and refuse to enter one. Can we not do something, at least, by way of encouraging them? You speak of "hard-working people struggling for an existence." All my life has been spent among hard-working people, and in many respects it seems to me they are having a pretty good time. Wages run from \$1.25 to \$1.50 per day, and almost every thing that a workman has to buy is cheap and good. Of course, there are times and seasons when certain things are away up; but with the great variety around the most of us, can we not select things that are reasonable? I have no sympathy at all with the few who "revel in their great wealth, and live at their ease;" and may God forbid that our crop of millionaires should continue to increase.—A. I. R.]

A CORRECTION.

On p. 344 of last issue, second column, third line from the bottom, it reads "lessens the first cost of the brood-nest." It should be first cost (first time filling the combs).

H. R. BOARDMAN.

M. C. D., O.—I should judge from what you say in your letter that your bees are afflicted with what is known as dysentery. The only cure I know is fair and warm weather.

A. S. M., Pa.—It is evident from your letter that the bees you speak of as crawling about and having swollen bodies are affected with the disease known as bee-paralysis. I know of no satisfactory cure for the disease. Sometimes removing the queen seems to remove the trouble; but in many cases it does no good whatever. If you have very many other colonies, and these bees do not get any better, I would recommend destroying them entirely.

M. L. B., Ill.—We are now using a very much better arrangement—T supers or combined crates, in connection with a honey-board. Wide frames—that is, double-tier—are not used very much, owing to the fact that burr-combs, used with the old-style frames, are apt to hold them down to the frames, making it somewhat difficult to remove them. But wide frames will come out all right providing the modern brood-frames are used in the lower part of the hive.

J. M. E., Ala.—It would take a good many years for basswood or linden trees to yield honey—perhaps twenty. We set out a basswood orchard something over 20 years ago, and it is not yielding honey very satisfactorily even yet. The experiment is rather too expensive to engage in very extensively.—I can not explain to you why some colonies are so much more energetic than others unless it be that the bees come from a more energetic queen. If you have a good queen, some colonies will do better than others, of course.

W. R. B., Ind.—The ants are a serious pest in certain parts of the South, but do not do much damage in the North. I would suggest that you find the nest, stick a crowbar in it, and make a hole about a foot deep in the center of it. Pour into this about ½ oz. of bisulphide of carbon. Tamp the hole tight, and you will have no further trouble from the ants. The bisulphide produces a gas, and kills them almost instantly, the gas permeating all the galleries of the nest.

B. D. C., N. H.—In our A B C of Bee Culture, under the heading of Poisonous Honey-plants, you will find the mountain laurel described as a poisonous honey-plant. I do not know that any deaths have ever occurred from it; but it certainly is not a honey to put upon the market if the report from Dr. Grammer is true, and I have no reason to doubt it, because his statement has been confirmed by others. Under the

circumstances, if you intend to go into bee-keeping extensively you had better locate somewhere else, for there is no doubt that the mountain laurel would yield well, and you might be able to sell the honey; but on the other hand you would be liable for heavy damages.

W. W., of N. Y., inquires how to feed bees in box hives. This can be done very nicely with the Gray entrance feeder shown on page 27 of the catalog we are sending you; or if you do not wish to go to that expense, use an ordinary common pan; pour in syrup made of sugar and water, about half and half, and spread over cheese-cloth. This should be put out in front of the entrance at night, because, if other bees are in the vicinity, it will cause robbing. The bees in the box hive will take the feed all in. Of course, such a plan of feeding would not answer in cold weather, but will do very well in late spring and summer.

J. O. S., Kan.—Yes, the comb in the super that was made last season will do to use this season; in fact, the bees will start in the sections a little sooner if there are a few of them containing a little drawn-out comb made the previous season. When a swarm issues with two queens, if you let them alone one of the queens will probably be disposed of; but if you can catch one of them you will be that much ahead, providing you have a place where you can use her in some other colony. The drones from a tested Italian queen are generally very dark, and to a beginner might appear to be black. You will find the Gault raspberry advertised extensively as formerly. I would refer you to our advertising columns and also to Special Notices.

H. B. H., Pa.—You say that the solution for imbedding wire in foundation in the battery that we send out does not seem to be strong enough, and you desire information. The solution as given in the directions will certainly give good results providing you follow very carefully what is said. After the solution has been in use an hour or so it may be necessary to strengthen it up a little by putting in more sulphuric acid. Put in enough until the battery gives the requisite power. Before you do this, make sure that all wire connections are perfectly clean. Otherwise you will fail to get satisfactory results. You say that you are experimenting with other chemicals. I do not think you will find any thing that will give you the strength of current that bichromate of potash and sulphuric acid combined in the proportions given in our little circular of directions do.

S. H. D., W. Va.—When bees are moved over a distance of three miles there is not the least danger of their returning to their old location. If I understand you, you expect to move them very much further than this. If you have an apiary of twenty-five or even fifty or one hun-

dred colonies I would advise you to have them sent by freight. When bees are moved much of a distance it is customary for some one to accompany them, going right along in the same car. No extra fare is charged for the person in attendance; but as your bees are going a much shorter distance than this, all that will be necessary will be to load them on the car and have some one receive them and unload them at destination. I take it that you are familiar with putting up bees so as to give them sufficient ventilation. There ought to be wire cloth on top and wire cloth at the entrance, and the frames should be fastened securely, of course, if not of the self-spacing type.

BEEES REMOVING EGGS; THAT MISSING LINK.

Do bees remove eggs from worker-cells and place them in queen-cells, and rear queens from them? Yes, they do. How do I know? I will tell you. Some years ago I found a colony in early spring that had become queenless—no eggs or young larvæ, and the bees vainly trying to raise a queen without these essentials. As the colony was small I took away all their combs but one, and then gave them two combs, making three in all, and shoved up a division-board so as to keep them warm. One of the combs given them was well filled with eggs and brood in all stages of development. The other comb contained some honey, and had been kept in an outbuilding during the winter. When sufficient time had elapsed for the bees to have sealed queen-cells from the young larvæ given them I opened the hive to see how many cells they had built. Imagine my surprise when I looked over the comb of brood given them, without finding any sign of building queen-cells or rearing a queen. I thought I would look farther, and lifted out the other combs, when I discovered, on the face of the comb that had been given, that had been wintered in a cold room, a single queen-cell well filled with royal jelly, and a larva in it not yet sealed, which was conclusive evidence to my mind that bees could not only move eggs from one cell to another, but that they could rear queens from them. This is the only instance in nearly thirty years' experience, and much of the time with hundreds of colonies of bees, that I can say positively I knew the bees had moved an egg, and used it for queen-rearing. From this experience I also learned that bees will do very differently at different times, or different colonies at the same time. Their instinct seems to vary in regard to many things, or they seem at times to be guided quite as much by impulse as instinct, which has led me to be somewhat skeptical as

to the value of non-swarmer hives or non-swarmer strains of queens, and devices that depend upon the bees doing every thing just as set down in the books. Indeed, there seem to be as many exceptions to their general rule of conduct or instinct as there are to the rules of English grammar.

J. E. CRANE.

Middlebury, Vt., Apr. 11.

EXTRA pages and an extra edition as usual.

RAMBLER writes that Southern California has started out for a big honey-flow, and that rains have been copious and timely. Extracting has been already commenced, and comb honey is being capped over.

A PAMPHLET, entitled "A New System of Management in Bee-keeping," by James Heddon, Dowagiac, Mich., has been received. Those who are interested in his system of bee-keeping can get the information by addressing the author as above.

I HAVE wondered whether it would be a bad idea to put in every issue a label on the "best article" in the judgment of the editor, as a sort of stimulus to the other correspondents. But then, there would be differences of opinion, and some would feel hurt, I fear.

WE have just received a note from C. P. Dadant, announcing the death of his mother, the estimable wife of Charles Dadant. She died on the morning of May 3, of a tumor of the liver. She was born in France, March 22, 1822, and was married to her surviving husband May 31, 1847, and came to this country in 1863. We feel sure that bee-keepers at large will unite with us in extending their sympathy to the bereaved husband and other members of the broken family circle.

THE editor of the *Progressive Bee-keeper*, while recognizing that good arguments are produced in favor of both the eight and ten frame hive, says that he himself prefers the ten-frame hive with a follower. "With such a hive," he says, "I can contract to six or enlarge to ten frames, to suit circumstances, by simply sliding the follower-board and putting in or taking out the frames. I use more hives with only eight frames in them than I do with more; yet if I were going to establish an apiary now, I would not buy eight-frame hives."

A BEAUTIFULLY illustrated and well-written article on bees appears in the May *Cosmopolitan*, by our old friend and co-worker W. Z.

Hutchinson. A common mistake of old writers on bees, when trying to instruct the general public, is to assume that that public knows more about bees than it really does. But friend Hutchinson has carefully covered the whole ground, and put it in such popular style that the reader is fascinated and interested at once. The photos from which the engravings are made are some of those prepared by Mr. Hutchinson some time ago, and which I have already referred to as being so accurate and clear. Copies of the *Cosmopolitan* containing this article can be obtained at the *Review* office at 20 cts., postpaid. The article is to be continued in the June number.

THE claim is sometimes made that a certain kind of hive will produce twice as much honey as another. Of course, this is not true. One *locality* may produce twice—yes, ten times as much honey as another. One *bee-keeper* in the same locality may, by the right management of his bee force at the right seasons of the year, produce twice as much honey as his neighbor who lets things take care of themselves. A certain peculiar construction of a hive may perhaps enable the intelligent bee-keeper himself to save half the labor. Construction may enable him, also, to secure a little more *marketable* honey, and perhaps a little more in the aggregate. The old statement, that bees will store as much honey in an old nail-keg as in the most improved hive, still stands practically uncontroverted. Improvement in the construction of hives looks, then, not to *more honey*, but to *less labor* in the getting of that honey.

ARE THOSE WHO LOSE IN WINTERING ALWAYS SLIPSHOD AND CARELESS?

In our last issue, in summing up the statistical reports on wintering, after referring to the good showing, I said: "As was to be expected, inexperienced and slipshod bee-keepers did not winter as well as those who read bee-journals." A subscriber, who has taken the journal for a number of years, and has read bee-books, and is supposed to be up with the times, takes this as a personal insult, because, he says, he has lost heavily. I am surprised that he should construe the sentence quoted as implying that every bee-keeper, himself included, who lost heavily, was therefore necessarily slipshod and behind the times. A careful reading of the sentence would hardly bear out this construction. I did not say that everybody who lost was slipshod, but I did say that "inexperienced and slipshod bee-keepers did not winter as well," etc. In other words, the slipshod lost heavily *because* of their carelessness, unlike our correspondent, who lost *in spite* of his care. His mistake was like that of the man who concluded that, as all eagles are birds, therefore all birds are eagles; hence a lark, being a bird, is an eagle. I did not mean to take this much

space to reply to this; but as others may perhaps have felt hurt in the same way, it is only necessary to explain that I did not mean to insult anybody, but was simply striking at *carelessness*, and not at our old friends and patrons.

At the last meeting of the North American, it will be remembered that Dr. C. C. Miller was appointed a committee of one to wait on the Western Classification Committee to see if he could secure some needed reduction in freight rates for bee-keepers and supply-dealers. May 8 last, this committee, assisted by Geo. W. York and Mr. Herman F. Moore, appeared before the railroaders, and were successful in securing one important reduction on honey in barrels, kegs, and cans. An interesting report by Mr. Moore will be given in our next.

MOISTURE IN CELLAR—DOES IT CAUSE DYSENTERY?
